Lebe mit deinem Jahrhundert, aber sei nicht sein Geschöpf; leiste deinen Zeitgenossen, aber was sie bedürfen, nicht was sie loben.

Live with your century, but do not be its creature; create for your contemporaries, not what they praise, but rather what they need.

Friedrich Schiller, *On the Aesthetic Education of Man*, Letter 9 (1794)

FORGOTTEN CREATORS

How German-Speaking Scientists and Engineers Invented the Modern World, And What We Can Learn from Them

Comments from Reviewers

“Todd H. Rider’s *Forgotten Creators* is a monumental treatise about and an exciting intellectual journey through the contributions of scientists and technologists in Germany and other Central European countries and German-speaking areas to universal progress. It is thoroughly researched, meticulously documented, and presented in an easy-to-perceive way. The pre-war and pre-Nazi German system of science support has lessons that would be difficult to emulate but worthy to ponder about even today. The long-range tragic consequences in science caused by National Socialism are well demonstrated as are the benefits in the West and in the East from the exodus of Jewish scientists before and the importation of others from Germany following World War II. The book is a virtually bottomless well for mining reliable information in the history of science and technology. The ‘forgotten creators’ are no longer forgotten. Todd is to be congratulated for his accomplishment and thanked for sharing it so generously with the international community.”

István Hargittai, Professor Emeritus of Chemistry, Budapest University of Technology and Economics,
author of *Buried Glory*, *Candid Science*, *Drive and Curiosity*, *Great Minds*,
Judging Edward Teller, *Martians of Science*, and *The Road to Stockholm*

“It was really with a great feeling of appreciation that I discovered the various chapters (physics, mathematics, biology, medicine, etc.) of this monumental work (over 6,000 pages!) by Todd H. Rider, which is dedicated to the German contributions to the advancement of scientific knowledge in the modern world. Thousands of valuable pieces of information all collected in a unique source make this book a precious tool both for reading and for research.”

Umberto Bartocci, Professor Emeritus of Mathematics and Mathematical History, University of Perugia

“Todd H. Rider’s *Forgotten Creators* is an encyclopedic consideration of Germany’s central place in the advancement of science and technology between 1800 and 1945. Drawing upon a wide range of sources, Rider has summarized that effort in a survey that will impress the reader just as much for the breadth of German intellectual achievement as for the influence that achievement has had upon the modern world.”

George W. Cully, retired Director, Office of History at Air University, Maxwell Air Force Base, Alabama

“The scope and ambition of *Forgotten Creators* is really incredible. It is a work of great scholarship, an effective narrative with many historical quotes by scientists and their contemporaries that make it a very engaging read. It is richly illustrated with so many photos of researchers, where they worked, maps, patents, etc. I think this book will be of great value to historians of science and public policy institutions. I also think that as the center of economic and scientific innovation seems to be shifting from West to East, many forward-thinking people in Asia will be reading this book closely as they consider their own path ahead.”

Brian Dempsey, President, Massachusetts Association of Biology Teachers

“The current fragmentation of scientific disciplines up to the point of marginalization raises the question whether examples from history do exist to overcome this situation. Todd Rider attempts an answer, posing the counter question: ‘Which lessons can be learned from the most productive German-speaking inventors of the nineteenth and early twentieth century?’ His intention is not only to start a discussion on the chances to successfully transfer former educational conditions to the present scientific system but also to remember the inventors. *Forgotten Creators*, published online, is an impressive compilation of German achievements, covering the natural sciences, mathematics, and engineering until WWII.”

Gernot Eilers, German Federal Ministry for the Environment, Nature Conservation, and Nuclear Safety

“Todd H. Rider reminds us with *Forgotten Creators* that many key technologies like jet flight, helicopters, rocket propelled gliders, guided missiles, night vision, special alloys and welding methods, or simply synthetic rubber or polymer products that are common today were actually developed in the first half of the twentieth century in Central Europe under the control of Germany. These technologies belonged among the most valuable treasures the Allies won in the Second World War and triggered a strategic arms race among the newly emerging superpowers in the subsequent decades of the Cold War (which some say had started already in 1945 in St. Georgen/Gusen, Austria). An indispensable new reference book for all who are interested in the history of technology and the twentieth century.”

Rudolf A. Haunschmied, Gusen Memorial Committee, author of *St. Georgen—Gusen—Mauthausen*

"Todd Rider's fundamental work, *Forgotten Creators*, is a formidable counter against the oblivion or even 'cancel science' regarding pre-Nazi and Nazi Germany. This era's technical and scientific achievements, although mostly along the sad Heraclid dictum '*bellum omnium pater*,' have their impacts even today. Apparently lots of documents of this period are still classified. I am convinced that the tenacious author will bring those to light and underpin his *magnum opus* further."

Manfred Höfert, former Head of Radioprotection at CERN, Geneva, Switzerland

"Todd Rider's *Forgotten Creators* is a really amazing overview of German technical history. Even contemporary historians will discover a lot of new references."

Rainer Karlsch, Institute for Contemporary History, Berlin, author of *Leuna: 100 Jahre Chemie*, *Sowjetische Demontagen in Deutschland 1944–1949*, *Playing the Game: The History of Adidas*, *Uranbergbau im Kalten Krieg*, *Uran für Moskau*, *Hitlers Bombe*, and *Für und Wider "Hitlers Bombe"*

"The book *Forgotten Creators* is a really impressive book, as Todd H. Rider tries to mention all relevant German-speaking scientists and engineers and their scientific fields up to 1945 in this mammoth project. In this form, nobody has dared to do this before. The author deserves my full respect for this. I am pleased that we were able to support him in his research."

Thomas Köhler, Peenemünde Historical-Technical Museum historian and head of the archive, author of *Vernichtender Fortschritt: Serienfertigung und Kriegseinsatz der Peenemünder "Vergeltungswaffen"*

"*Forgotten Creators* is an examination of mid-twentieth-century German science and technology, studying the question of how this era came to be so productive. Using extensive reproduction of original materials and source accounts, the author is not only able to provide an overview of what is known about wartime activities, but is also able to indicate avenues for future historical research. The careful and comprehensive referencing permits the materials presented to be used in academic studies. A notable feature of this work is the fluid format provided by online publication, allowing revisions and new materials to be added. An especially important emphasis of the book is what can be learned from both the German-speaking scientists and the World War II era in general that could improve scientific productivity and creativity now."

Thomas Kunkle, Los Alamos National Laboratory, retired

"*Forgotten Creators* shows us some aspects of the German culture in form and content: it reflects the spirit of the German soul in the best of the senses, focused on the recent history of science mainly in Germany and the U.S. The style reminds me of some of the biggest creations of German culture: ambitious, brave, sublime, erudite, extensive, rigorous in the analyses and exhorting in the discourses. Great! It grasps the sociological problems of science nowadays, and it offers lucid pessimistic views and wise observations of the facts. There are two different leitmotivs: 1) the modern decline of our scientific and technical advances; 2) the highest importance of German science in the most important contributions of the twentieth century scientific and technological advances. Hence, the author posits interesting hypotheses that relate the decline of science and the recent history of Germany and its influence in the world. Risk-taking interpretations that are worth reading and thinking about."

Martín López-Corredoira, Instituto de Astrofísica de Canarias,
author of *The Twilight of the Scientific Age*

"In the book *Forgotten Creators*, Todd H. Rider presents interesting perspectives that contribute to rethinking the story of the German nuclear project, as well as the role that heavy water had in it. The book also confirms the importance of the military actions carried out against heavy water production at Vemork."

Gunhild Lurås, Heavy Water Exhibition Curator,
Norwegian Industrial Workers Museum, Vemork

"Todd Rider has done a heroic job of bringing 'secret Nazi research' out of tinfoil-hat territory and into the realm of rigorous scholarship by compiling the vast primary-source material on a subject that has generally daunted mainstream historical research. And that shadowy field is only a sliver of the vast sweep of German science and technology covered in this monumental work. *Forgotten Creators* is a triumph of exactingly documented fact-finding and analysis, but it also rewards both the casual reader and the serious researcher with dynamic cross-referencing, side-by-side translations, and splendid illustrations. Rider has achieved a difficult balancing act—opening up new areas of inquiry while staying within the ever-accumulating evidence."

Diane McWhorter, biographer of Wernher von Braun and 2002 Pulitzer Prize winner

"Encyclopedia. This was the very first word coming to my mind when reading Todd H. Rider's book. In one publication the reader is given the opportunity to review official documents as well as getting familiar with stories told by people who were involved in the development of modern technology. The book serves as a compendium of knowledge for all who are passionate about any kind of research and inventions, not only about the ones which saw the light during the Second World War and the German national socialism era. There is no doubt that many of German speaking scientists presented in the book have strongly contributed to the colossal technological progress and the development of new disciplines of science. However, when you read the book, I would encourage you not to focus on these magnificent discoveries only. Names like Wernher von Braun, Hubertus Strughold, and Otto Ambros trigger a negative connotation to many as their activities during the period of Nazi Germany are still not completely transparent. Read, think about it, and draw your own conclusions."

Marek Michalski, author of *Labor Camp Treblinka I*,
researcher for the Treblinka Museum and Gross-Rosen Museum

"With his work, based on very comprehensive, thoroughly researched sources, Todd Rider has presented an astonishing study of the history of German science, especially in the first half of the twentieth century, which also reveals many connections that have been unjustly forgotten or little noticed. This also applies to numerous persons whose achievements are hardly known."

Günter Nagel, author of *Wissenschaft für den Krieg*, *Himmlers Waffenforscher*,
Atomversuche in Deutschland, and *Das geheime deutsche Uranprojekt 1939–1945*

"A very valuable part of the book is devoted to the development of nuclear weapons in Germany during WWII, 1939–1945. While the histories of both the US/British Manhattan Project and the Soviet atomic project have been to a large extent declassified, little is actually known about the German work. Rider has done historians a favor by marshalling all of the evidence he could find in US, German, and Russian archives regarding the German atomic project. The inescapable conclusion is that the Germans were much farther advanced in nuclear weapons development than is generally thought."

Lee Pondrom, Professor Emeritus of Physics, University of Wisconsin-Madison,
author of *The Soviet Atomic Project: How the Soviet Union Obtained the Atomic Bomb*

"Todd Rider's book *Forgotten Creators*, the creation of which I was able to observe and support for more than two years, is extraordinary in every respect. The sheer size of the book shows how important the role of German-speaking scientists was in the development of new technological advances. But it also shows the author's will to present as complete an account of this history as possible. He has succeeded in doing so. The work therefore serves both as an introductory book and as a reference book. It is highly recommended."

Georg Ribienski, Documentation Center Manager, Jonastalverein historical society, Thuringia

"Todd Rider has created an incredible document that details the technical contributions of Central Europeans in the nineteenth and twentieth centuries. The scope and scholarship are breathtaking. This document contains useful insights into how innovation and progress actually occur, as well as useful lessons that should be implemented by leaders in corporations, government agencies, and other organizations. It is past time to eliminate or minimize bureaucratic practices that obstruct innovation."

William C. Schneck, Jr., Colonel (ret.), U.S. Army Corps of Engineers (USAR)

"*Forgotten Creators* by Todd Rider is an extraordinary work of detailed research and new insights into the technological advances contributed by German-speaking scientists. His lengthy and in-depth study of history often overlooked or not even seen in more cursory reviews is a refreshing read. His attempt to create the fullest account possible has resulted in a fine reference book that also serves to introduce new research for the reader. Rider's contention, right up front in the Executive Summary—that inventions and discoveries had their highest concentration of revolutionary innovations from scientists and engineers from the German-speaking central European research world in the nineteenth and early twentieth centuries—demands the reader's attention. He then fills an enormous amount of over 6,000 pages with supporting details. Amazing subject matter and new revolutionary insights dug up through meticulous research make *Forgotten Creators* a 'must read' for serious historians and curious researchers alike."

D. Ray Smith, Oak Ridge Historian, retired Y-12 Historian, author, and newspaper columnist

"Todd Rider's extensively researched and amazingly detailed book opens a new world for everybody interested in the history of science. Never before has anyone dug as deeply into the sources as Todd has, such that he even discovered interesting details about our father, then a young officer, and revealed some new aspects about him to us, his children. We are very grateful for Todd's interest, dedication, and thorough research."

Andrea (Stoelzel) Edwards and Bernhard Stoelzel,
children of former Peenemünde staff member Heinz Stoelzel

"This is a truly fascinating work! Dr. Rider has produced an insightful and comprehensive survey of a highly scientifically productive domain in spacetime. It is well worth understanding why that was, and what aspects of that culture should be preserved or revived."

David Strozzi, Lawrence Livermore National Laboratory

"This truly voluminous study provides an in-depth overview of techno-scientific achievements and innovations which originated from the German-speaking world. It is a rich and fascinating history of the transnational circulation of knowledge over a period of no less than two centuries."

Helmuth Trischler, Head of Research, Deutsches Museum, Munich, author of *Luft- und Raumfahrtforschung in Deutschland 1900–1970* and *Building Europe on Expertise: Innovators, Organizers, Networkers*

"A most important and deserving book. Todd Rider's research on the German rocket and nuclear programs in World War II is especially impressive because of the number and depth of the sources cited and the meticulousness of their evaluation. Really pioneering work has been done here!"

Matthias Uhl, Deutsches Historisches Institut, Moscow, author of
Stalins V-2: Der Technologietransfer der deutschen Fernlenkwaffentechnik and
Die Organisation des Terrors: Der Dienstkalender Heinrich Himmlers 1943–1945

"Todd Rider's compendium traces the phenomenal and explosive contribution of the Central European scientific culture of the first half of the twentieth century to the modern world. The multinational renaissance was ended by the Second World War, but the participants became scientific refugees in the victorious states, driving technology around the world during the Cold War. A unique and valuable resource!"

Mark Wade, author of *Encyclopedia Astronautica*, http://www.astronautix.com

"Todd Rider has produced a meticulously researched and cogently argued *tour de force* on the men and the circumstances that drove the modern German Renaissance in science and technology. Brought out of the long shadow of the Third Reich, the story of this Golden Age of human enquiry is convincingly shown to have as much relevance to our present times as it did then. A remarkable achievement."

Stephen Walton, Senior Curator, U.K. Imperial War Museum

Executive Summary

Wo ich schaffe, bin ich wahr. Where I create, I am true.

Rainer Maria Rilke. 8 August 1903. Letter to Lou Andreas-Salomé.

Chapter 1: Why We Should Remember What Was Forgotten. As shown in this chapter, the world does not appear to be producing truly revolutionary scientific innovations at the same rate it once did (certainly if measured in terms of revolutionary innovations per researcher or per amount of funding). Instead the academic research sector seems increasingly fixated on maximizing its rate of publishing papers regardless of their quality, redundancy, or relevance; the corporate research sector appears more and more focused on very low-risk, immediately marketable products; and the government research sector seems increasingly incapacitated by bureaucracy and budget cuts. Rather than trying to create solutions for these modern systemic problems from scratch, one may study what conditions facilitated the successes of innovators in other times and places.

Many people like to believe that their own country has been the most innovative, and indeed, inventions and discoveries have been made around the world and throughout history. Yet as illustrated by the examples in this book, the highest concentration (or at the very least, one of the highest concentrations) of revolutionary innovations appears to have come from scientists and engineers who were trained in the predominantly German-speaking central European research world in the nineteenth and early twentieth centuries. Unfortunately, the history of those innovations has been significantly obscured by World Wars I and II, the Cold War, language barriers, and cultural stereotypes, leaving the modern world less aware of the details and less able to fully reproduce the research conditions that led to so many revolutionary achievements. Therefore the objectives of this book are to:

- Elucidate the major creators and creations produced by that German-speaking world in various fields of science and engineering (Chapters 2–9 and Appendices A–E).
- Determine the systemic factors that promoted so much revolutionary innovation in that particular place and time (Chapter 10).
- Evaluate the previous successes and failures of transferring that scientific knowledge and those systemic methods to other research systems (Chapter 11).
- Propose methods by which modern governments, organizations, and/or individuals could better emulate the success of the earlier German-speaking research world (Chapter 12).

A variety of study scopes and methods would be possible and enlightening, but this book focuses on revolutionary innovators who were educated in that earlier German-speaking world[1] between approximately 1800 and 1945, as well as their subsequent careers (in some cases to the dawn of the twenty-first century). As explained in detail in this chapter, this study does not argue that the modern research system has produced no revolutionary innovations, but rather that it can and should be improved. This study is not intended to support nationalist or ethnic bragging rights, the Third Reich, or any notion that research conditions in the German-speaking world were ever perfect. At best this book can only give a concise overview of a vast field encompassing the actions of thousands of scientists and engineers across many countries over a period of two centuries, as well as investigations into that time period by countless subsequent scholars.

---

[1] Defined herein as German, Austrian, and Swiss researchers; eastern European and other researchers who trained in the German-speaking world; and scientists and engineers in the closely coupled Dutch research system.

The German-speaking world produced remarkable numbers of revolutionary innovators and innovations in a wide range of fields, as enumerated in eight chapters:

Chapter 2: Creators and Creations in Biology and Medicine
Advances from genetics to antibiotics

Chapter 3: Creators and Creations in Chemistry and Materials Science
Breakthroughs from color film to synthetic rubber

Chapter 4: Creators and Creations in Earth and Space Science
Discoveries about the universe from continental drift to stellar distances

Chapter 5: Creators and Creations in Physics and Mathematics
Revolutionary ideas from relativity to quantum mechanics

Chapter 6: Creators and Creations in Electrical and Electromagnetic Engineering
Inventions from semiconductors to computers

Chapter 7: Creators and Creations in Mechanical Engineering
Systems from automobiles to submarines

Chapter 8: Creators and Creations in Nuclear Science and Engineering
Reactions and applications from fission to fusion

Chapter 9: Creators and Creations in Aerospace Engineering
Vehicles from jet planes to moon rockets

Chapter 10: Creating the Creators. Based on evidence presented in this chapter, a number of specific factors within the German-speaking world promoted revolutionary innovation:

1. Science was socially glorified, from children's activities and amateur science clubs to prestigious jobs and government-lauded scientific heroes.

2. A century-long steady exponential increase in funding gave scientists, employers, and sponsors much more freedom to pursue higher-risk and/or longer-term research.

3. Many Ph.D. students were encouraged to propose their own research topics and to pursue them independently.

4. Scientists received their final degrees nearly a decade earlier in life, and independent research funding up to two decades earlier, than modern scientists do.

5. Scientists who made major contributions to multiple disciplines, and fraternization among scientists from different disciplines, were much more common than in the modern world.

6. Instead of peer review, an autocratic yet farsighted scientific management culture of "enlightened despots" granted stable jobs and funding to the most promising creators and creations.

7. Both scientists and sponsors used a systems analysis approach to focus on the most important problems and the most effective innovations to address those problems.

8. The lack of natural resources spurred the creation of a wide range of innovative alternatives.

9. International rivalry (both economic and military) was a powerful driving force for innovation.
10. German-speaking companies were less afraid of losing their own innovations to each other than of being outstripped by foreign countries, giving them a strong motivation to innovate.

Chapter 11: Immortalizing the Creations and Forgetting the Creators. As documented in this chapter, the modern world eagerly adopted the creations of the earlier German-speaking world, yet ultimately largely forgot both the creators and the systemic approaches that had made such creations possible. Over the course of waves that occurred before, during, and after the Third Reich, all of the creations, most of the creators, and some of the systemic approaches were transferred from the German-speaking world to the United States and other countries in a German scientific diaspora. Those countries spent many decades fully perfecting and mass-producing the innovations that had been created by the earlier German-speaking world, resulting in our modern world of jet aircraft, electronics, and pharmaceuticals. Most of the creators who had already died or who remained in German-speaking areas were largely forgotten by the non-German-speaking world, which often mistakenly attributed their creations to whichever non-German-speaking individuals or organizations had acquired their technical information. Most of the creators who emigrated out of German-speaking areas led well-funded but quiet lives perfecting their creations and were also ultimately forgotten. Especially during the 1940s–1960s, the United States and other countries practiced some of the general approaches that had made the earlier German-speaking world successful, thereby cultivating new innovators and innovations of their own.

By the 1970s, most of the German-speaking creators had retired or died, their creations had been refined to the point of diminishing incremental returns, and global research systems had abandoned most of the German-like practices they had adopted, significantly reducing their efficiency at producing entirely new innovators and innovations. The Cold War as a strong motivating force for innovation had also relaxed around 1970, and any truly revolutionary new innovators (or innovations) that were produced by the global research system found it increasingly difficult to obtain proper support as time went by. From the 1990s onward, with the Cold War over and officials both public and private haggling over every research dollar while spending heavily or even wastefully in other areas, the academic, corporate, and government research sectors each became increasingly dysfunctional in their own ways.

Chapter 12: Learning from the Creators. Based on the successes of the earlier German-speaking world, this final chapter offers lessons that could be applied at any scale from the national level down to an individual's career. At a nationwide or statewide level, the following policies could improve the ability of the modern scientific system to produce revolutionary innovators and innovations:

1. The social and financial status of science research should be elevated greatly. Better quality and greater variety of educational science experiment kits for children should be produced and more widely advertised and used. Student science competitions (especially ones like science fairs that emulate real scientific research) should be given much greater emphasis, and the winners of those competitions should be very publicly praised and rewarded. The salaries and working conditions of science and other teachers should be improved in order to attract very talented people to those positions and to recognize and reward the most effective teachers. Important scientific discoveries and inventions, as well as the people responsible for them, should be given much more coverage in television news programs, movies, newspapers, magazines, and popular internet sites.

2. If the amount of funding and permanent job positions better matched the number of graduating students and career researchers (by increasing funding wherever possible, or otherwise by limiting the number of students going into research), scientists would be able to spend much more of their time and energy doing productive research, and much less of their time and energy pursuing elusive funding and positions. It would also be much more acceptable to sponsors, institutions, and the scientists themselves for researchers to pursue longer-term work without an immediately demonstrable payoff, as well as more innovative higher-risk work that would be less guaranteed to yield results than very incremental, low-risk work.

3. Science students should be trained from an early age to be very creative and very self-reliant researchers. Students should be strongly encouraged to select their own research topics and methods. Research advisors should provide as much advice and assistance as is necessary (but only what is necessary) to ensure that their students are pursuing productive research topics using suitable methods. Research advisors should not use students as unpaid or low-wage labor to benefit the advisors' own research grants or lists of publications.

4. The average age at which scientists receive their final degree and obtain independent research funding should be reduced back toward their early to mid-twenties. That would greatly increase the number of productive working years during which those scientists have the greatest creativity, the most energy, and the fewest non-research obligations.

5. The system should train and reward at least some percentage of multidisciplinary scientists who can make major contributions in multiple fields, apply knowledge and methods from one field to another, and use their broader view to guide fields away from less productive areas and toward more productive ones. All scientists should be strongly encouraged to make their research comprehensible to people outside their field, and to interact with scientists in other fields in a variety of environments, in order to cross-pollinate ideas among different fields.

6. While there is certainly a place for methodical peer review, entrusting virtually all funding and hiring decisions to peer review risks overlooking those creative new scientists and ideas that are so revolutionary that they cannot easily and immediately get broad consensus from the scientific status quo. The modern research system should set aside some percentage of research funding to be allocated by "enlightened despots" who are good at identifying potentially revolutionary innovators and innovations. Such enlightened despots should have the clear authority to grant financial and political support to any people or projects they deem worthy, and to grant that support for many years without having to demonstrate that there is an immediate payoff, or even that all funded research will eventually pay off. Wherever possible, any remaining peer review should be done by reviewers unaware of the researchers' names and affiliations, so that they can more fairly evaluate the actual research in question.

7. By using systems analysis, key decision makers in government, industry, and academia could help focus more resources on the most important problems and potential solutions. If individual scientists were taught to practice systems analysis, they could use that method to guide their careers and their research projects in more promising directions, and to ensure that no potentially useful regions of the conceptual "phase space" had been overlooked.

8. In the face of dwindling natural resources and the rising long-term costs of climate change, pollution, and waste, government-funded programs and government regulations for industrial programs should prioritize the development of very innovative methods of reducing the consumption of natural resources and minimizing the creation of waste products.

9. Peaceful economic rivalry and regional pride could constructively motivate nations or states to accelerate their research programs. Regional high-tech centers could promote interactions among programs they contain, and rival high-tech centers could compete for the best scientists, projects, research funding, and economic income from resulting inventions and products.
10. Companies should view very innovative, longer-term research and development (R&D) as a worthwhile investment in staying ahead of competitors, not a financial liability whose resulting products could be copied by competitors that did not fund their own R&D. Improved tax, patent, regulatory, or other government incentives could make it much more lucrative for the first company that develops any given major innovation, and/or less lucrative for copycats.

In addition to the above lessons for national or state research systems, Chapter 12 also offers additional lessons for individual companies, organizations, and laboratories; for individual scientists and engineers; and for scholars who study past, present, and potential future innovation systems.

The appendices focus on some potentially quite advanced creations of the German-speaking world during World War II that are currently much less well understood by modern historians, and whose complexities necessitate a considerably longer treatment than could be given in Chapters 2–9:

> **Appendix A** presents archival documents that suggest that Germany had the largest and most advanced biotechnology programs in the world at that time, was developing neural interfaces to control prosthetic limbs and weapons systems, possessed a significant offensive program in biological warfare, and discovered advanced V-series nerve agents during the war.
>
> **Appendix B** gives an overview of evidence that transistors and other microelectronics innovations may have originated in the German-speaking world, and that information on those technologies may have been transferred to and exploited by Allied countries after the war.
>
> **Appendix C** presents documents that appear to show that the German-speaking world developed and tested a variety of directed-energy technologies, including particle beams, electromagnetic pulse weapons, major steps toward lasers, focused sound waves for applications ranging from ultrasound imaging to acoustic weapons, and electromagnetic railguns.
>
> **Appendix D** provides considerable evidence that Germany may have developed and even successfully tested fission bombs during the war (which would have made it the first country in world history to possess nuclear weapons), and that it may have even had a megaton-level hydrogen bomb in an advanced stage of development when the war ended.
>
> **Appendix E** presents archival documents that appear to show that wartime Germany made considerable progress toward developing the aerospace technologies that have formed the "nuclear triad" for most of the postwar decades: intercontinental jet bombers, intercontinental ballistic missiles, and submarine-launched missiles.

Although the evidence in the appendices does not constitute conclusive proof, it should prompt further archival research to clarify the true extent of those wartime programs.

The **Bibliography** of over 400 pages covers relevant books, articles, government reports, and archival documents.

To maximize the audience, longevity, and impact of this book, it is available for free on the internet. Hopefully it will spur discussion, learning, and further work in the important areas that it covers. Suggestions for improvements are very welcome.

For creators
everywhere,
past, present,
and future.

  - 2.5.1 Vitamins . . . 343
  - 2.5.2 Steroid Hormones . . . 351
  - 2.5.3 Nonsteroidal Hormones . . . 368

2.6 Developmental Biology and Embryology . . . 375
2.6.1 Developmental Biology . . . 375
2.6.2 Caesarean Sections and Neonatal Incubators . . . 387
2.7 Aerospace Medicine, Prostheses, and Other Physiology . . . 390
2.7.1 Aerospace Medicine . . . 390
2.7.2 Prostheses . . . 397
2.7.3 Miscellaneous Anatomy, Physiology, and Zoology . . . 401
2.8 Botany . . . 405
2.8.1 Photosynthesis . . . 405
2.8.2 Other Aspects of Botany . . . 413

3 Creators and Creations in Chemistry and Materials Science 419
3.1 Inorganic Chemistry . . . 427
3.1.1 Discoveries of Elements . . . 427
3.1.2 Creation of the Periodic Table of the Elements . . . 441
3.1.3 Other Important Contributions to Inorganic Chemistry . . . 447
3.2 Organic Chemistry . . . 456
3.2.1 Synthetic Dyes and the Origins of Organic Chemistry . . . 456
3.2.2 General Organic Chemistry . . . 467
3.2.3 Organometallic Chemistry . . . 497
3.2.4 Synthetic Fuels . . . 502
3.2.5 Liquid Crystals . . . 505
3.2.6 Technology Transfer out of the German-Speaking World . . . 507
3.3 Chemistry of Foods and Drinks . . . 509
3.3.1 Synthetic Flavors . . . 509
3.3.2 Synthetic Drinks . . . 513
3.3.3 Synthetic Fats . . . 513
3.3.4 Synthetic Protein Products . . . 520
3.3.5 Preservatives . . . 520
3.4 Explosives . . . 524
3.4.1 Explosive Chemical Compounds . . . 524
3.4.2 Fuel-Air Explosives . . . 538
3.4.3 Shaped Explosive Charges . . . 558
3.4.4 Radio Control and Electric Timers for Explosives . . . 564
3.5 Chemical Warfare Agents and Pesticides . . . 567
3.5.1 First-Generation Chemical Weapons . . . 567

3.5.2 Insecticides . . . 583
3.5.3 G-Series Nerve Agents . . . 584
3.5.4 V-Series Nerve Agents . . . 590
3.5.5 Other Chemical Weapons . . . 593
3.6 Physical Chemistry . . . 594
3.6.1 General Physical Chemistry . . . 594
3.6.2 Batteries and Fuel Cells . . . 615
3.7 Film Photography . . . 624
3.7.1 Development of Photography . . . 624
3.7.2 Transfer of Photography-Related Technologies . . . 626
3.8 Materials Science . . . 643
3.8.1 Polymers . . . 643
3.8.2 Ceramics and Crystallography . . . 667
3.8.3 Glass . . . 680
3.8.4 Metals . . . 689
3.9 Other Creations in Chemistry . . . 708
3.9.1 Chromatography . . . 708
3.9.2 Colloids . . . 717
3.9.3 Synthetic Lubricating Oils . . . 720
3.9.4 Synthetic Detergents and Paper Recycling . . . 723
3.9.5 Chemical Fabric Treatments . . . 728
3.9.6 Firefighting Chemicals . . . 728
3.9.7 “Superglue” . . . 732

4 Creators and Creations in Earth and Space Science 733
4.1 Geological Science . . . 734
4.1.1 Stratigraphy and Continental Drift . . . 735
4.1.2 Geophysics . . . 739
4.1.3 Universal Transverse Mercator (UTM) for Map Coordinates . . . 749
4.2 Paleontology . . . 751
4.2.1 Animal and Plant Fossils . . . 751
4.2.2 Hominid Fossils . . . 758
4.2.3 Biogeography . . . 758
4.3 Ocean and Hydrological Science . . . 764
4.3.1 Oceanography . . . 764
4.3.2 Antarctica . . . 770

4.3.3 Ice Ages . . . 770
4.4 Atmospheric Science . . . 774
4.5 Planetary Science . . . 784
4.5.1 Heliocentric Solar System and Planetary Orbits . . . 784
4.5.2 Moon and Mars Maps . . . 785
4.5.3 Asteroids . . . 793
4.5.4 Outer Solar System . . . 800
4.6 Astrophysics . . . 804
4.6.1 Cosmic Rays . . . 804
4.6.2 Stellar Physics . . . 808
4.6.3 Maps of Stars and Galaxies . . . 812
4.6.4 Cosmology . . . 813

5 Creators and Creations in Physics and Mathematics 821
5.1 Applied Mathematics and Classical Mechanics . . . 823
5.1.1 Creators and Creations Before 1800 . . . 823
5.1.2 Creators and Creations After 1800 . . . 825
5.2 Electromagnetism . . . 851
5.2.1 Electric Currents and Magnetic Fields . . . 858
5.2.2 Electromagnetic Waves . . . 859
5.2.3 Electron, Proton, and Neutron Beams . . . 862
5.3 Special and General Relativity . . . 865
5.3.1 Special Relativity . . . 865
5.3.2 General Relativity . . . 876
5.4 Non-Relativistic Quantum Physics . . . 883
5.4.1 Early Steps Toward Quantum Theory . . . 890
5.4.2 Final Development of Quantum Theory . . . 894
5.5 Statistical and Thermal Physics . . . 901
5.5.1 Thermodynamic Properties . . . 912
5.5.2 Bosons . . . 915
5.5.3 Fermions . . . 919
5.5.4 Cryogenics . . . 921
5.6 Relativistic Quantum Physics or Particle Physics . . . 923
5.6.1 Quantum Field Theories of Fundamental Forces Other Than Gravity . . . 923
5.6.2 Quantum Gravity . . . 937

6 Creators and Creations in Electrical and Electromagnetic Engineering 939

6.1 Electrical Equipment and Circuits . . . 944

6.2 Lighting Technology . . . 957

6.2.1 Tools for Analyzing the Visible Spectrum, Infrared, and Ultraviolet Light . . . 957

6.2.2 Incandescent Light Bulbs . . . 957

6.2.3 Gas Discharge and Fluorescent Light Tubes . . . 958

6.2.4 Light Emitting Diodes (LEDs) . . . 960

6.3 Communications and Recording Technologies . . . 972

6.3.1 Telegraphs . . . 972

6.3.2 Telephones . . . 976

6.3.3 Radio . . . 978

6.3.4 Mobile Telephone Systems . . . 980

6.3.5 Optical Communications Systems . . . 980

6.3.6 Disc Phonograph Records and Players . . . 990

6.3.7 Magnetic Tape Recording . . . 990

6.3.8 Motion Picture Cameras and Projectors . . . 996

6.3.9 Television . . . 996

6.3.10 Video Telephone System . . . 1013

6.3.11 Scanners, Facsimile (Fax) Machines, and Printers . . . 1013

6.3.12 Photocopiers . . . 1018

6.3.13 Optical Discs and Digital File Formats . . . 1019

6.4 Lasers, Holography, and Laser Spectroscopy . . . 1023

6.4.1 Lasers . . . 1023

6.4.2 Holography . . . 1029

6.4.3 Laser Spectroscopy . . . 1033

6.5 Solid State Physics and Microelectronics . . . 1034

6.5.1 Solid State Physics . . . 1034

6.5.2 Semiconductor Materials and Devices . . . 1044

6.5.3 Transistors . . . 1048

6.5.4 Postwar Transfer of Microelectronics Technologies . . . 1076

6.5.5 Capacitors . . . 1077

6.5.6 Printed Circuits . . . 1088

6.5.7 Integrated Circuits . . . 1095

6.5.8 Light Emitting Diodes (LEDs) and Laser Diodes . . . 1104

6.5.9 Superconductivity . . . 1112

6.5.10 Piezoelectricity 1122
6.6 Infrared Vision and Targeting 1131
6.6.1 Development of Infrared Technologies 1131
6.6.2 Transfer of Infrared Technologies 1147
6.7 Computers and Robotics 1157
6.7.1 Calculating Machines 1157
6.7.2 Computers 1162
6.7.3 Cryptography 1184
6.7.4 Robotics 1198
6.8 Radar and Sonar Technologies and Countermeasures 1217
6.8.1 Radar 1217
6.8.2 Radar Countermeasures 1234
6.8.3 Microwave Heating 1238
6.8.4 Sonar 1241
6.8.5 Sonar Countermeasures 1247
6.8.6 Ultrasound Imaging 1250
6.8.7 Acoustic Weapons 1250
6.8.8 Radio and Acoustic Proximity Fuses and Homing Devices 1254
6.9 Microscopes, Telescopes, and Other Optical Instruments 1260
6.10 Electron Microscopes 1286
6.10.1 Electron Microscopes and Scanning Electron Microscopes 1286
6.10.2 Scanning Tunneling Electron Microscopes and Atomic Force Microscopes . . 1294

7 Creators and Creations in Mechanical Engineering 1297
7.1 Writing and Printing 1299
7.1.1 Printing Press 1300
7.1.2 Typewriters 1300
7.1.3 Stationery Supplies 1306
7.1.4 Improved Printing Processes 1310
7.2 Musical Instruments 1317
7.2.1 Woodwind Instruments 1318
7.2.2 Brass Instruments 1326
7.2.3 Pianos 1330
7.2.4 Metronomes 1330
7.3 Internal Combustion Engines and Motor Vehicles 1333
7.3.1 Internal Combustion Engines, Motorcycles, Motorboats, Automobiles, Trucks 1333

7.3.2 Chainsaws 1365
7.3.3 Tanks 1367
7.3.4 Diesel Train Locomotives 1382
7.4 Heat Transfer 1385
7.5 Civil Engineering and Architecture 1392
7.5.1 Stress, Strain, and Bridge Design 1392
7.5.2 Autobahn High-Speed Road System 1397
7.5.3 Kitchen Design 1402
7.5.4 Other Creations in Civil Engineering and Architecture 1404
7.6 Projectile Weapons 1410
7.6.1 Guns 1410
7.6.2 Artillery 1426
7.6.3 Shaped-Charge Anti-Tank Weapons 1428
7.6.4 Electromagnetic Railguns 1439
7.6.5 Flamethrowers 1441
7.7 Ocean Engineering 1447
7.7.1 Early Experimental Submarines 1447
7.7.2 Military Submarines 1452
7.7.3 Bathyscaphes 1481
7.7.4 Rotor Ships 1483
7.8 Other Creations in Mechanical Engineering 1485
7.8.1 Watches 1485
7.8.2 Vacuum Pumps and Pressure Valves 1487
7.8.3 Bicycles 1491
7.8.4 Polar Planimeter 1495
7.8.5 Liquid Agitators and Turbines 1495
7.8.6 Gyroscopes and Gyrocompasses 1496
7.8.7 Sports Shoes 1496

8 Creators and Creations in Nuclear Science and Engineering 1503
8.1 Nuclear Diagnostics and Therapeutics 1505
8.1.1 X-Rays 1505
8.1.2 Radioisotopes and Isotope Labeling 1511
8.1.3 Nuclear Magnetic Resonance (NMR)/Magnetic Resonance Imaging (MRI) . . 1515
8.2 Radiation Detectors 1518
8.2.1 Electrical Detection of Radiation 1518

8.2.2 Optical Detection of Radiation 1519
8.2.3 Mössbauer Spectroscopy 1522
8.3 Particle Accelerators and Ion Traps 1524
8.3.1 Particle Accelerators 1524
8.3.2 Ion Traps 1528
8.4 Models of the Atomic Nucleus 1530
8.4.1 Liquid Drop Model 1530
8.4.2 Shell Model 1535
8.5 Nuclear Fission Reactions 1537
8.6 Nuclear Fusion Reactions 1542
8.7 Nuclear Engineering in the United States and United Kingdom 1546
8.8 Nuclear Engineering in the Third Reich 1563
8.8.1 Flaws in the Conventional Historical View of the German Program 1563
8.8.2 Fundamental Knowledge and Planning 1565
8.8.3 Sources of Uranium and Thorium 1569
8.8.4 Enrichment of ^{235}U 1571
8.8.5 Fission Reactors for Breeding ^{239}Pu and/or ^{233}U 1575
8.8.6 Electronuclear Breeding of ^{239}Pu and/or ^{233}U 1580
8.8.7 Production of Other Potentially Nuclear-Related Materials 1582
8.8.8 Fission Bomb Designs 1586
8.8.9 Hydrogen Bomb Designs 1592
8.8.10 October 1944 Test Explosion on the Baltic Coast 1594
8.8.11 Circa November 1944 Test Explosion in Poland 1595
8.8.12 March 1945 Test Explosions in Thuringia 1596
8.8.13 Wartime/Postwar Axis Belief in the Reality of German Nuclear Weapons . . 1599
8.8.14 Wartime/Postwar Allied Belief in the Reality of German Nuclear Weapons . 1601
8.8.15 Further Research That Is Needed 1609
8.9 Nuclear Engineering in the Soviet Union 1630

9 Creators and Creations in Aerospace Engineering 1639
9.1 Lighter-Than-Air Craft 1640
9.2 Aerodynamics and Aircraft Design 1651
9.2.1 First Aircraft 1651
9.2.2 Aerodynamics Experiments and Theory 1657
9.2.3 Specialized Aircraft 1678
9.2.4 High-Speed Aircraft Design 1694

9.3 Jet Engines and Jet Aircraft . . . 1707
  9.3.1 Jet Engines . . . 1707
  9.3.2 Jet Aircraft . . . 1768
9.4 Parachutes and Ejection Seats . . . 1782
  9.4.1 Parachutes . . . 1782
  9.4.2 Ejection Seats . . . 1792
9.5 Helicopters . . . 1797
  9.5.1 Proto-Helicopters and Autogyros . . . 1797
  9.5.2 Henrich Focke's Helicopter Team . . . 1810
  9.5.3 Anton Flettner's Helicopter Team . . . 1823
  9.5.4 Friedrich von Doblhoff's Helicopter Team . . . 1827
  9.5.5 Backpack Helicopters . . . 1827
  9.5.6 Electric Helicopters . . . 1832
  9.5.7 Transfer of Helicopter Technologies to Other Countries . . . 1834
9.6 Small Missiles and Smart Bombs . . . 1835
  9.6.1 Wartime Missiles and Smart Bombs . . . 1835
  9.6.2 Postwar Missiles and Smart Bombs . . . 1848
9.7 Large Liquid Propellant Rockets . . . 1856
  9.7.1 Pre-War and Wartime German Rocket Programs . . . 1858
  9.7.2 Postwar U.S. and U.K. Rocket Programs . . . 1861
  9.7.3 Postwar Soviet Rocket Programs . . . 1874
  9.7.4 Postwar French Rocket Programs . . . 1883
9.8 Submarine-Launched and Solid Propellant Rockets . . . 1890
  9.8.1 Submarine-Launched Missiles . . . 1890
  9.8.2 Solid Propellant Rockets . . . 1901
9.9 Rocket Planes and Space Planes . . . 1918
  9.9.1 Rocket Planes . . . 1918
  9.9.2 Space Planes . . . 1927
9.10 Space Exploration . . . 1938
  9.10.1 Interplanetary Trajectories . . . 1938
  9.10.2 Space Stations . . . 1942
  9.10.3 Non-Chemical Rockets . . . 1953

10 Creating the Creators **1959**
10.1 Comparison of Innovation System Size . . . 1961
  10.1.1 Total Population and Scientific Innovators in the German-Speaking World . . 1961

10.1.2 Comparison with the Modern World 1964
10.2 Systemic Factors Promoting Innovation 1965
10.2.1 Cultural Attitudes Toward Science Education and Research 1965
10.2.2 Funding Levels 1974
10.2.3 Mentoring Style 1979
10.2.4 Average Age for Final Degree 1986
10.2.5 Interdisciplinary Approach 1994
10.2.6 Scientific Leadership and Decision-Making Style 1998
10.2.7 Systems Analysis 2014
10.2.8 Limited Natural Resources 2018
10.2.9 International Rivalry 2021
10.2.10 Industrial Unity of Purpose 2023
10.2.11 Other Factors 2026

11 Immortalizing the Creations and Forgetting the Creators 2033
11.1 Creations and Creators Transferred from the German-Speaking World 2034
11.1.1 Before the Third Reich 2034
11.1.2 During the Third Reich 2041
11.1.3 After the Third Reich 2050
11.2 General Approaches Transferred from the German-Speaking World 2171
11.2.1 Cultural Attitudes Toward Science Education and Research 2172
11.2.2 Funding Levels 2181
11.2.3 Mentoring Style 2189
11.2.4 Average Age for Final Degree 2192
11.2.5 Interdisciplinary Approach 2198
11.2.6 Scientific Leadership and Decision-Making Style 2200
11.2.7 Systems Analysis 2231
11.2.8 Limited Natural Resources 2233
11.2.9 International Rivalry 2234
11.2.10 Industrial Unity of Purpose 2238
11.2.11 Other Factors 2244
11.3 Failure to Sustain Approaches Transferred from the German-Speaking World 2245
11.3.1 Observations of Decline 2245
11.3.2 Explanations for Decline 2259

12 Learning from the Creators 2271

12.1 Summary of the Creators, Their Creations, and Their Approaches 2272
12.2 Lessons from the Creators 2277
  12.2.1 Lessons for State, National, and Global Innovation Systems 2277
  12.2.2 Lessons for Individual Organizations and Laboratories 2283
  12.2.3 Lessons for Individual Scientists and Engineers 2288
  12.2.4 Lessons for Scholars of Past, Present, & Potential Future Innovation Systems 2293
12.3 Afterword 2300

Appendices **2303**

A Advanced Creations in Biology and Medicine **2305**
A.1 Biotechnology 2306
A.2 Prostheses and Neural Interfaces (Bionics) 2485
A.3 Biological Warfare 2515
A.4 Chemical Warfare 2583
  A.4.1 German Chemical Weapons 2583
  A.4.2 Allied/Axis Threats of Mutual Assured Destruction 2632

B Advanced Creations in Electrical Engineering **2653**
B.1 Transistors 2654
B.2 Printed Circuits and Multi-Pin Connectors 2764
B.3 Integrated Circuits 2815
B.4 Light Emitting Diodes (LEDs) and Laser Diodes 2888
B.5 Postwar Transfer of Microelectronics Technologies 2923

C Advanced Creations in Directed Energy **3019**
C.1 Particle Beams and X-Rays 3020
C.2 Electromagnetic Pulse 3096
C.3 Lasers 3102
C.4 Focused Sound Waves 3181
C.5 Magnetic Levitation and Electromagnetic Railguns 3204

D Advanced Creations in Nuclear Engineering **3253**
D.1 Conventional Historical View of the German Program 3256
  D.1.1 Alsos Mission 3257
  D.1.2 Farm Hall Recordings 3336
  D.1.3 Postwar Public Statements by a Few German Nuclear Scientists 3346

D.2 Fundamental Scientific Knowledge and Program Planning 3362
D.3 Sources of Uranium and Thorium 3404
D.4 Enrichment of Uranium-235 3476
    D.4.1 Production of Uranium Hexafluoride for Uranium-235 Enrichment 3478
    D.4.2 Uranium-235 Enrichment via Centrifugation 3494
    D.4.3 Uranium-235 Enrichment via Electromagnetic Separation 3554
    D.4.4 Uranium-235 Enrichment via Gaseous Diffusion 3618
    D.4.5 Uranium-235 Enrichment via Photochemical Processes 3664
    D.4.6 Possible Locations of Uranium Enrichment Facilities 3670
D.5 Fission Reactors for Breeding Pu-239 and/or U-233 3794
    D.5.1 Scientific Knowledge About Breeding Pu-239 and U-233 3794
    D.5.2 Known and Suspected Fission Reactors 3840
D.6 Electronuclear Systems for Breeding Pu-239 and/or U-233 3954
D.7 Production of Other Potentially Nuclear-Related Materials 4026
D.8 Fission Bomb Design 4154
D.9 Fusion Fuel and Bomb Design 4278
D.10 Possible October 1944 Test Explosion on the Baltic Coast 4390
D.11 Possible ∼November 1944 Test Explosion in Poland 4440
D.12 Possible March 1945 Test Explosion in Thuringia 4478
D.13 Axis Belief in the Reality of German Nuclear Weapons 4572
D.14 Allied Belief in the Reality of German Nuclear Weapons 4692
    D.14.1 U.S. Presidential Intelligence 4698
    D.14.2 Alsos and Other Manhattan Project Intelligence 4714
    D.14.3 Dutch Intelligence 4832
    D.14.4 French Intelligence 4854
    D.14.5 German and Japanese Submarines 4858
    D.14.6 High-Level Interrogations 4894
    D.14.7 U.S. Inspections of Possible Nuclear Facilities 4962
    D.14.8 German and Austrian Scientists in the United States 4992
    D.14.9 Other Intelligence Services 5010
    D.14.10 Fritz Lang and the Leak That Almost Revealed Everything 5076
    D.14.11 Allied Intelligence Officials Who Would/Should Have Known 5082
D.15 Analysis of Current Evidence; Recommended Further Work 5086
    D.15.1 Overarching Considerations Regarding the German Nuclear Program 5086
    D.15.2 Enrichment Methods to Produce U-235 5116

D.15.3 Breeding Methods to Produce Pu-239 or U-233 5129
D.15.4 Analysis of Test Explosions from Primary Sources 5138
D.15.5 Estimating Device Design Parameters from Primary Sources 5154
D.15.6 Possible Evidence for Other Device Designs 5169
D.15.7 Conclusions and Recommended Further Research 5173

E Advanced Creations in Aerospace Engineering 5185

E.1 Intercontinental Jet Bombers 5187
E.2 Advanced Liquid Propellant Rockets 5265
E.3 Space Planes and Space Shuttles 5588
E.4 Submarine-Launched and Solid Propellant Rockets 5618
E.5 Longer-Term Space Projects 5737
E.5.1 Orbital Spacecraft and Space Stations 5738
E.5.2 Fission Thermal Rocket Propulsion 5757
E.5.3 Fission Pulse Rocket Propulsion 5770
E.5.4 Electric Rocket Propulsion 5772
E.5.5 Antimatter Rocket Propulsion 5773
E.6 Analysis of Advanced Jet Developments 5774
E.7 Analysis of Advanced Rocket Developments 5781
E.7.1 Fundamentals of Rocket Performance 5781
E.7.2 Increasing the Size of the Rocket 5794
E.7.3 Increasing the Exhaust Velocity of the Rocket Engine 5798
E.7.4 Adding a Booster Stage to the Rocket 5800
E.7.5 Adding Strap-on Boosters to the Rocket 5802
E.7.6 Adding Wings to the Rocket 5803
E.7.7 Decreasing Stresses During Atmospheric Reentry 5804
E.8 Conclusions 5819
E.8.1 Payloads 5819
E.8.2 Delivery Vehicles 5820
E.8.3 Forgotten History 5822

Zusammenfassung 6316

Abstract 6317

Acknowledgments

Es ist ein merkwürdiges Gefühl, schlechthin in allem auf die Hilfe der anderen angewiesen zu sein. Aber jedenfalls lernt man in solchen Zeiten dankbar werden und wird das hoffentlich nicht wieder vergessen. Im normalen Leben wird einem oft gar nicht bewußt, daß der Mensch überhaupt unendlich mehr viel mehr empfängt, als er gibt, und daß Dankbarkeit das Leben erst reich macht. Man überschätzt wohl leicht das eigene Wirken und Tun in seiner Wichtigkeit gegenüber dem, was man nur durch andere geworden ist.

It is a strange feeling to be so completely dependent on the help of other people. However, at least it teaches one to be grateful, and I hope I shall never forget that. In ordinary life we hardly realize that we receive a great deal more than we give, and that it is only with gratitude that life becomes rich. It is very easy to overestimate the importance of our own achievements in comparison with what we owe to others.

Dietrich Bonhoeffer. 13 September 1943 letter to his parents.
Eberhard Bethge, ed. 2016. *Widerstand und Ergebung: Briefe und Aufzeichnungen aus der Haft* [*Resistance and Resignation: Letters and Papers from Prison*]. Gütersloh: Gütersloher Verlag.

As a child, I read about scientists and engineers (including some of those in this book) who tackled the most important problems that were within their power, and as a result produced revolutionary discoveries and inventions that changed the world. Inspired by those examples, I have spent most of my life endeavoring to pursue innovative scientific research projects of my own (p. 6314). Over the years, unfortunately, I have personally witnessed how the modern U.S. research system is dysfunctional in many different ways, and how that dysfunction can discourage the initiation of potentially revolutionary research projects and also prematurely terminate innovative projects that have been initiated.

Eventually it dawned on me that perhaps the most important research problem is the research system itself—even modest improvements in the research system could have large effects on countless individual innovators, and amplified through them, an enormous impact on the whole world. Rather than relying on the very limited data set of my own personal experiences or even those of my colleagues, I decided to examine a far larger data set, the history of science, in hopes of better understanding the problems with and potential solutions for the modern research system.

This book is the result of that effort. It is very much a work in progress, imperfect and incomplete, yet I offer it in hopes that it will inspire ideas, discussion, and further work in the areas that it covers. **If readers have any suggestions for corrections, improvements, or additions, please send me an email (ToddHRider@gmail.com or thor@riderinstitute.org), and I will try to incorporate those suggestions into a future improved edition.**

Just as the modern world is entirely dependent upon the creations of numerous earlier inventors and scientists, this book would not have been possible without all of the earlier research and publications of large numbers of scholars and investigators (such as those listed in the Bibliography), as well as the documents, information, suggestions, and assistance that many of those people have provided directly to me. I would especially like to thank:

Aberdeen Proving Ground (Maryland): Dr. Brian R. Scott (retired) for graciously answering questions and providing documents.

Albert Einstein College of Medicine (New York): Prof. Jan Vijg for reading a partial draft and providing a graph from his own research on innovation.

Alma College (Alma, Michigan): Prof. Bruce Cameron Reed for reading a draft and offering suggestions.

Applewood Interactive (Massachusetts): Casey Clarke for website and internet assistance.

Archiv der Max-Planck-Gesellschaft (Berlin-Dahlem): Simon Nobis and Susanne Uebele for patient assistance in locating files and photographs.

Archiv der Österreichischen Akademie der Wissenschaften (Vienna): Stefan Sienell for providing photos and information and for reading a draft.

Atomkeller Museum (Haigerloch): The museum staff for offering information and assistance.

Battelle Memorial Institute: Joseph E. Backofen, Jr. (retired) for generously providing many helpful documents and for offering encouragement.

Bornholm Defence Museum: Jens Skaarup for providing information on the German and Soviet occupations of Bornholm island.

Bornholm Museum: Sanne Steenberg Hansen for assistance in finding books, information, and experts on the German and Soviet occupations of Bornholm island.

B Reactor Museum Association (Hanford, Washington): Dr. Robert Franklin and other members for examining evidence of the WWII German nuclear program and providing suggestions and information.

Budapest University of Technology and Economics: Prof. István Hargittai for graciously reading drafts and offering very helpful suggestions and encouragement.

Bundesarchiv Militärarchiv (Freiburg): Ms. Bröske, Carina Notzke, Jan Warßischek, and other staff for their assistance in searching the collections.

CERN (Geneva): Dr. Manfred Höfert, former Head of Radioprotection, for reading sections of the book and generously providing suggestions and information.

Deutsches Historisches Institut (Moscow): Dr. Matthias Uhl for graciously providing documents and information, and for reading drafts of the book.

Deutsches Historisches Museum (Berlin): The museum staff for providing information and assistance.

Deutsches Museum (Munich): Irene Püttner, Dr. Matthias Röschner, Wolfgang Schinhan, Dr. Helmuth Trischler, Dr. Elisabeth Vaupel, and other staff for all of their help with the collections, documentation, photos, and information at the Museum, and for reading drafts and offering suggestions.

Deutsches Technikmuseum (Berlin): Dr. Volker Koesling, Jörg Schmalfuß, Antje Stritzke, Dr.

Tiziana Zugaro, and other staff for all of their help with the collections, documentation, photos, and information at the Museum.

Foundation Centre for German Communication and Related Technology (Netherlands) for providing useful documents.

Friends of German Culture (Huntsville, Alabama): John Schweinsberg for providing information and encouragement.

Friedrich Loeffler Institute (Riems): Prof. Thomas Mettenleiter, Elke Reinking, and other staff for graciously providing a guided tour, supplying documentation, and answering questions.

Gedenkdienstkomitee Gusen (Austria): Rudolf Haunschmied for generously taking the time to answer questions and provide information, and for reading book drafts.

German Research Project (California): Henry Stevens for being extremely generous in providing large amounts of very useful archival documents, microfilm reels, indices of report series, books, and other information, and for reading a book draft and offering suggestions and encouragement.

Herder-Institut für historische Ostmitteleuropaforschung (Marburg): Dr. Silke Fengler for being incredibly helpful by providing a number of documents and for reading drafts and offering suggestions.

Historisch-Technisches Museum Peenemünde: Dr. Philipp Aumann, Thomas Köhler, and other staff for all of their time and assistance with documentation, information, and materials at the Museum, and for reading drafts of the book.

Historisch-Technisches Museum Versuchsstelle Kummersdorf: Christian Bergner, Norbert Wagner, Gerhard Zwicker, and other staff for graciously providing a guided tour, answering questions, and reading book drafts.

Hofstra University (Hempstead, New York): Prof. David Cassidy for taking the time to read a draft and offer very helpful suggestions and information.

Hollins University (Roanoke, Virginia): Prof. Amy Gerber-Stroh for answering questions and providing information.

Imperial College London: Clive R. Woodley for graciously answering questions and providing documents.

Instituto de Astrofísica de Canarias (Canary Islands): Prof. Martín López-Corredoira for reading drafts and offering suggestions.

Institute für Zeitgeschichte (Berlin): Dr. Rainer Karlsch for graciously reading many drafts and for providing very useful advice, information, and documents.

Johannes Gutenberg-Universität (Mainz): Prof. Johannes Preuss for reading drafts and offering very helpful information and encouragement.

Jonastalverein (Arnstadt): Karl-Heinz Huhn, Georg Ribienski, Rolf-Harald Ruthke, and other staff for being very helpful in providing documents and information and for reading drafts.

KZ-Gedenkstätte Mittelbau-Dora (Nordhausen): The memorial staff for graciously providing a guided tour and answering questions.

Lawrence Livermore National Laboratory (California): Dr. David Strozzi for reading through the book and offering feedback and encouragement.

Los Alamos National Laboratory (New Mexico): Dr. Tom Kunkle (retired) for reading sections of the book and providing very helpful documents and suggestions.

Ludwig-Maximilians-University (Munich): Prof. Kärin Nickelsen for answering questions and providing information.

Masaryk Institute and Archives of the Czech Academy of Sciences (Prague): Dr. Michaela Šmidrkalová for helpful information and suggestions.

Max-Planck-Institut für Wissenschaftsgeschichte (Berlin-Dahlem): Dr. Alexander Blum for reading drafts and offering very helpful information on the history of physics, and Dr. Dieter Hoffmann (Max-Planck-Institut für Wissenschaftsgeschichte) for information on Fritz Houtermans.

Mendel Museum (Brno): The museum staff for providing information and assistance.

MIT (Cambridge, Massachusetts): Dr. Peter Catto for taking the time to read a draft and offer advice, and Dr. Florian Metzler for reading sections and providing suggestions, papers, and information.

National Air and Space Museum (Washington, DC): Dr. Michael Neufeld and other staff for providing documents and answering questions.

National Museum of American History (Washington, DC): Dr. Frank Blazich, David Haberstich, and other staff for hosting a discussion of the book and offering helpful suggestions.

National Museum of Nuclear Science & History (Albuquerque, New Mexico): Anna Part and other staff and members for examining evidence of the WWII German nuclear program and providing suggestions and information.

National Museum of the U.S. Air Force (Wright Patterson Air Force Base, Ohio): Brett Stolle and other staff for answering questions.

Norsk Teknisk Museum (Oslo): Dr. Ketil Andersen for reading a draft and providing helpful information.

North Cape Publications (California): Joe Poyer for taking the time to answer questions.

Norwegian Industrial Workers Museum (Vemork): Gunhild Lurås, Kristine Mathisen, and other staff for providing information and reading book drafts.

Oak Ridge National Laboratory (Oak Ridge, Tennessee): Ray Smith (retired) for graciously answering questions and reading drafts.

Office for Environmental Geology & Security Research (Marburg): Fritz Pfeiffer for providing helpful information.

Princeton University (New Jersey): Library staff for their generous assistance with the Special Collections.

Proomnia Media (Linz, Austria): Andreas Sulzer and other staff for reading drafts, generously providing documents, and answering questions.

Robert Koch Institut (Berlin): Henriette Senst and Heide Tröllmich for being very helpful in providing information and answering questions.

Sachverständigenbüro Staude (Limbach-Oberfrohna): Dietmar Staude and Tobias Keidel for reading drafts and for offering very helpful information regarding potential locations for underground facilities.

Salem State University (Salem, Massachusetts): Prof. Benjamin Levin for assistance with Russian translations.

Schering Archiv, Bayer Pharma (Berlin): Thore Grimm for providing photos and information.

Schweizerisches Bundesarchiv (Bern): Dr. Peter Fleer and Marco Majoleth for their generous assistance in searching for and providing archival documents.

Schweizerische Nationalbibliothek (Bern): Andreas Berz for searching the collections and finding extremely helpful documents and information.

Society for Science & the Public (Washington, DC): Michele Glidden and Anna Rhymes for reading a draft and offering very helpful feedback.

Staatsarchiv, Staatskanzlei Obwalden (Sarnen, Switzerland): Mario Seger for generous assistance with files and searches.

Standortübungsplatz (formerly Truppenübungsplatz) Ohrdruf: the command staff and range control officers for allowing me to visit and for providing a guided tour of the base.

Stanford University (California): Prof. Nicholas Bloom for permission to use one of his graphs.

Stevens Institute of Technology (Hoboken, New Jersey): Prof. Alex Wellerstein for providing documents and information.

Technisches Museum Wien (Vienna): Dr. Hubert Weitensfelder, Dr. Anne-Katrin Ebert, and other staff for all of their help with the collections, documentation, photos, and information at the Museum, and for reading book drafts.

U.K. Imperial War Museum Archive (Duxford): Stephen Walton for answering questions and providing assistance with archival searches, and for reading book drafts.

U.K. National Archives (Kew): Archival staff for assistance with searches.

Union College (Schenectady, New York): Prof. Mark Walker for taking time to answer questions and offer advice.

Universitätsarchiv Stuttgart: Dr. Norbert Becker for searching the archive and providing a relevant photograph.

University of Brescia (Italy): Prof. Guido Abate for all of his help providing sources, translations, and other information.

University of Kent (U.K.): Dr. Charlie Hall for answering questions and providing useful information.

University of Minnesota Carlson School of Management: Dr. Michael Park and Prof. Russell Funk for graciously providing graphs.

University of Oxford: Prof. David Deutsch for answering questions and offering information about the early history of interpretations of quantum physics.

University of Perugia (Italy): Dr. Umberto Bartocci, Professor Emeritus of Mathematics and Mathematical History, for reading sections of the book and generously offering suggestions and information.

University of Southern California (Los Angeles), Warner Bros. Archive: Bree Russell for graciously finding and providing documents and answering questions.

University of Vienna: Prof. Mitchell Ash and Prof. Carola Sachse for reading book drafts, answering questions, and providing very helpful information.

University of Washington (Seattle): William Beaty for generously offering information and references regarding the early history of transistors.

University of Wisconsin-Madison: Prof. Lee Pondrom for graciously reading drafts and offering suggestions and encouragement.

U.S. Air Force Historical Research Agency (Maxwell Air Force Base, Alabama): Tammy Horton, Archie DiFante, Sylvester Jackson, Juan Rackley, Melanie Rooney, and Samuel Shearin for all of their assistance in obtaining relevant files and answering questions; independent research service providers Randy Asherbranner and George Cully for reading drafts and for their very helpful suggestions and encouragement, and George for providing scans of paper documents.

U.S. Army Combined Arms Research Library (CARL, Fort Leavenworth, Kansas): The library staff for answering questions and providing documents.

U.S. Army Communications Electronics Command (Fort Belvoir, Virginia): William C. Schneck, Jr., Colonel (ret.), for reading book sections and offering many helpful suggestions for corrections, additions, and improvements.

U.S. Holocaust Memorial Museum (Washington, DC): The archival and museum staff for answering questions and providing documents.

U.S. Library of Congress: Lawrence Marcus, Nanette Gibbs, and other staff for locating documents, answering questions, showing me the collections, and providing very helpful information.

U.S. National Archives at Atlanta (Morrow, Georgia): Shane Bell, Joel Walker, and other staff for all of the information and assistance they provided.

U.S. National Archives at Boston (Waltham, Massachusetts): Archival staff for their assistance in locating documents.

U.S. National Archives at College Park (Maryland): Paul Brown, Martin Gedra, Russell Hill, Nathaniel Patch, and all of the other archival staff for their assistance in locating documents and answering questions.

U.S. National Park Service: Brandon Bies and Dr. Robert K. Sutton for providing information about Fort Hunt.

U.S. National WWII Museum (New Orleans): Joey Balfour and other staff for answering questions.

U.S. Naval Air Station Point Mugu (California): Dr. Brent Meeker (retired) for answering questions and providing information about the history of the research center.

Villa Folke Bernadotte (former Manfred von Ardenne house and laboratory in Berlin): Annette Gowin and other staff for giving a guided tour and granting access to their archive of historical photos and documents.

Yad Vashem Holocaust Resource Center (Israel): Emmanuelle Moscovitz for providing documents and information.

Zweites Deutsches Fernsehen (ZDF, Mainz): Stefan Brauburger for being willing to read book drafts and offer feedback and advice.

Hinnerk Albert for generously offering useful information and documents.

Jim Beblavi (Colorado) for historical and archival information.

David N. R. Bleecker (Maryland) for his generosity in sharing important archival documents.

Dr. Gordon James Brown (Townsville, Australia) for taking the time to answer questions, provide documents and photographs, and put me in touch with the right people.

Kwang-Hua W. Chu for reading the book and offering helpful suggestions.

Rita Costa-Hollmann (California) for offering information and encouragement.

Brian Dempsey (Boxborough, Massachusetts) for very helpful conversations and suggestions, and for reading book drafts.

Andrzej Ditrich (Poland) for providing photos and information about numerous WWII research sites in Poland.

Frank Döbert (Jena) for generously providing large numbers of documents as well as very helpful suggestions, and for reading many drafts.

Max Du (New York) for reading book drafts and offering very helpful suggestions and encouragement.

The family of Hans Ehrhardt for their consideration in providing documents and information.

Dr. Gernot Eilers (Wolfenbüttel) for offering extremely helpful documents, detailed information, and extensive suggestions on several book drafts and the wording of translations.

Marsha Freeman (Virginia) for taking the time to read a book draft and offer encouragement.

Dr. Arthur Gelb (Belmont, Massachusetts) for graciously reading a partial draft and providing very helpful suggestions.

Friedrich Georg for generously providing archival documents and for reading drafts of this book

and offering suggestions.

Michael Haupt (Dortmund) for reading parts of the book and providing information, especially archival documents about modified A-4 rockets and some very interesting suggestions regarding neptunium-237.

Gunther Hebestreit (Bleicherode) for graciously providing many photos, documents, and suggestions, and for reading book drafts.

Erin Heinold (Westford, Massachusetts) for helpful conversations and suggestions.

Philip Henshall (U.K.) for reading sections of the book and offering information and encouragement.

Marko Herceg (Zagreb) for reading the book and providing insightful suggestions and information.

Guy Inchbald (Upton-upon-Severn, U.K.) for reading portions of the book and offering many tremendously helpful suggestions.

Dr. Adam Kretschmer (Prague) for reading book drafts and providing very helpful information, documents, and translations.

Norberto Lahuerta (Valencia, Spain) for discovering and very generously providing vast numbers of important documents from archives, old periodicals, and other sources (especially on advanced German nuclear, aerospace, and prosthetics developments, among others), for helping with some of the translations, and for reading many drafts of this book and offering countless very helpful suggestions.

Kathy Lowney (Massachusetts) for kindly translating a Russian document.

Russo Luca (Palermo, Italy) for reading sections of the book and offering useful information.

Manuel Lukas (Giesen) for his generosity in sharing many important archival documents and suggestions.

Jaroslav Mareš (Prague) for reading book drafts and providing very helpful documents and information.

Diane McWhorter (Washington, DC) for reading large sections of the book and for providing many helpful archival documents and suggestions.

Thomas Mehner (Zella-Mehlis) for taking time to answer questions and provide information.

Marek Michalski (Zabrze, Poland) for generously providing numerous documents and suggestions and for reading drafts of the book.

Marc Millis (NASA, retired) for taking time to read a partial draft and offer very useful advice.

Dr. Günter Nagel (Potsdam) for reading book drafts and being tremendously helpful in providing documents, photos, information, and assistance.

Yorck Neudenberger (Kassel) for reading sections of the book and for generously providing 1940s-1950s aerial surveillance photos and other information.

Dr. Douglas M. O'Reagan (Massachusetts) for answering questions and providing very helpful documents.

William J. Pellas (Louisville, Kentucky) for reading portions of the book and providing very helpful information, documents, and suggestions.

Philip Pesavento (Waxahachie, Texas) for finding and providing great information on the history of photochemical isotope enrichment approaches.

Heiko Petermann (Detmold) for reading book drafts, generously providing documents, and answering questions.

Jaroslav Pilař (Czech Republic) for graciously offering information and documents.

Dwight Rider (no relation) for providing very helpful documents and information.

Prof. Wolfgang Schwanitz (New Jersey) for answering questions and providing information.

John Smith for reading sections of the book and sending useful suggestions and references.

David Spetman (Huntsville, Alabama) for reading partial drafts of this book and offering very helpful suggestions.

Andrea (Stoelzel) Edwards and Bernhard Stoelzel, the children of Heinz Stoelzel, for their consideration in answering questions and providing information, and for reading drafts of the book.

Tony Toluba for answering questions and providing helpful information.

Sidney Trevethan (Anchorage, Alaska) for providing copies of his books and for answering questions.

Hema Viswanath (Massachusetts) for offering advice and assistance with library searches.

Mark Wade (www.astronautix.com) for reading book drafts, answering questions, and providing helpful information and encouragement.

Ed West for reading sections of the book and offering encouragement and information.

Robert Wilcox for graciously answering questions and providing information.

Dr. Kevin Wilson, Dr. Catherine Trotter Wilson, and Peter Wilson for reading and offering extremely helpful suggestions on drafts of this book.

Ryan Wood (Colorado) for generously providing copies of NARA documents and other information.

Dr. Benjamin Zusman for reading several book drafts and offering very helpful suggestions and encouragement.

My father, Jerry Rider, my uncle, Bill Rider, and my in-laws for reading partial drafts, offering excellent suggestions, and being very supportive throughout the project.

My children, Ben and Sarah, for their patience throughout this project.

Most of all, I am incredibly grateful to my wife, Lori, for being so supportive and doing so much to make this book possible, from initially suggesting the idea of a book, through taking photos and assisting with research, to offering editorial advice on the final product.

Chapter 1

Why We Should Remember What Was Forgotten

Heiße Magister, heiße Doktor gar	I'm called a Master, even Doctor too
Und ziehe schon an die zehen Jahr	And now I've nearly ten years through
Herauf, herab und quer und krumm	Pulled my students by their noses to and fro
Meine Schüler an der Nase herum—	And up and down, across, about
Und sehe, daß wir nichts wissen können!	And see there's nothing we can know!
Das will mir schier das Herz verbrennen.	That all but burns my heart right out.
Zwar bin ich gescheiter als all die Laffen,	True, I am more clever than all the vain creatures,
Doktoren, Magister, Schreiber und Pfaffen;	The doctors and masters, writers and preachers;
Mich plagen keine Skrupel noch Zweifel,	No doubts plague me, nor scruples as well.
Fürchte mich weder vor Hölle noch Teufel—	I'm not afraid of devil or hell.
Dafür ist mir auch alle Freud entrissen,	To offset that, all joy is rent from me.
Bilde mir nicht ein, was Rechts zu wissen,	I do not imagine I know aught that's right;
Bilde mir nicht ein, ich könnte was lehren,	I do not imagine I could teach what might
Die Menschen zu bessern und zu bekehren.	Convert and improve humanity.

Johann von Goethe. 1808. *Faust Part One.* Nacht, Faust.
English verse translation adapted from George Madison Priest.

Science and engineering have changed the world in countless ways. While some scientific discoveries and engineering inventions may be harmful or dangerous if misused, on the whole they appear to have improved our lives. Very few people who are alive now would voluntarily choose to give up indoor plumbing, electric lights, rapid transportation, and modern medicine. Based on such historical precedents, we have good reason to hope that science and engineering could make our lives even better in the future. Thus it is in the best interests of everyone, even those who are not scientists and engineers, for the scientific research and development system to function as well as possible.

The ultimate goal of this book is to help improve our understanding of the past, the present, and the potential future of scientific research and development, and through that improved understanding, to enhance the effectiveness of the research and development system in bringing new discoveries and inventions to our lives and those of our children and grandchildren.

1.1. This chapter begins by evaluating the state of scientific innovation in the modern world:

  1.1.1. Problems with the modern innovation system from everyday experience.

  1.1.2. Problems with the modern innovation system from published analyses.

  1.1.3. Problems with modern academic research.

  1.1.4. Problems with modern corporate research.

  1.1.5. Problems with modern government research.

1.2. Then this chapter turns to consider scientific innovation in the earlier German-speaking world:

  1.2.1. Studying the earlier German-speaking world can help to improve the modern innovation system.

  1.2.2. The scope and framework of this book are explained.

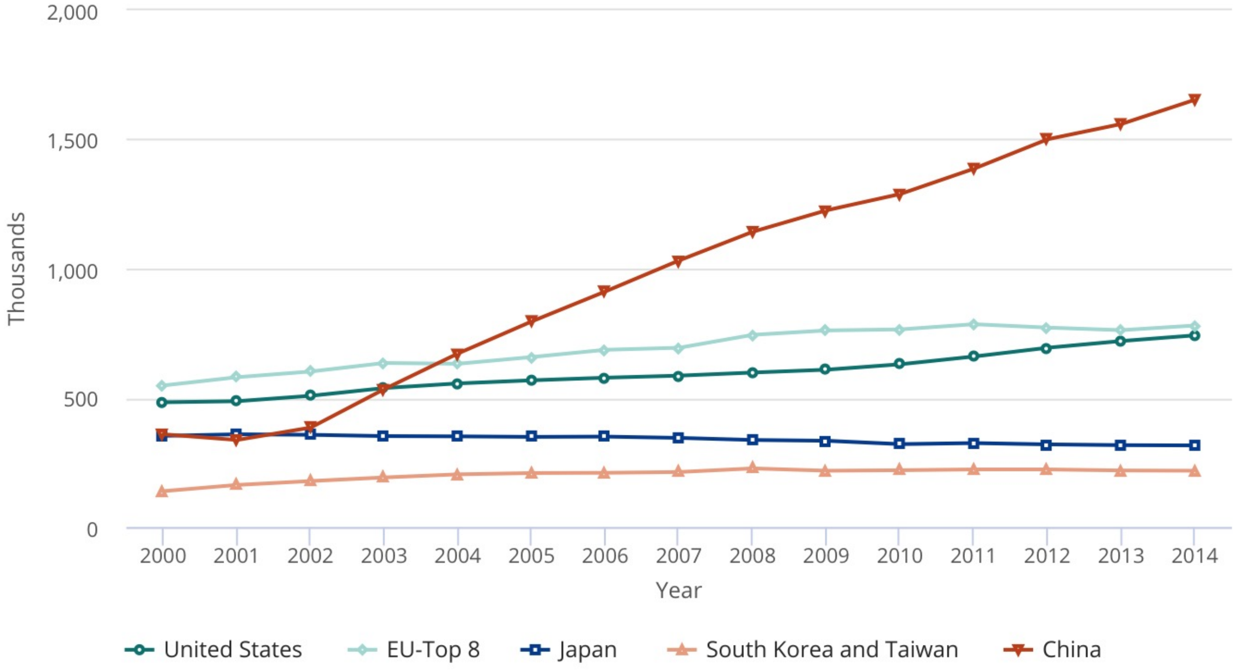
  1.2.3. A number of disclaimers are presented for clarity and precision.

1.1 Scientific Innovation in the Modern World

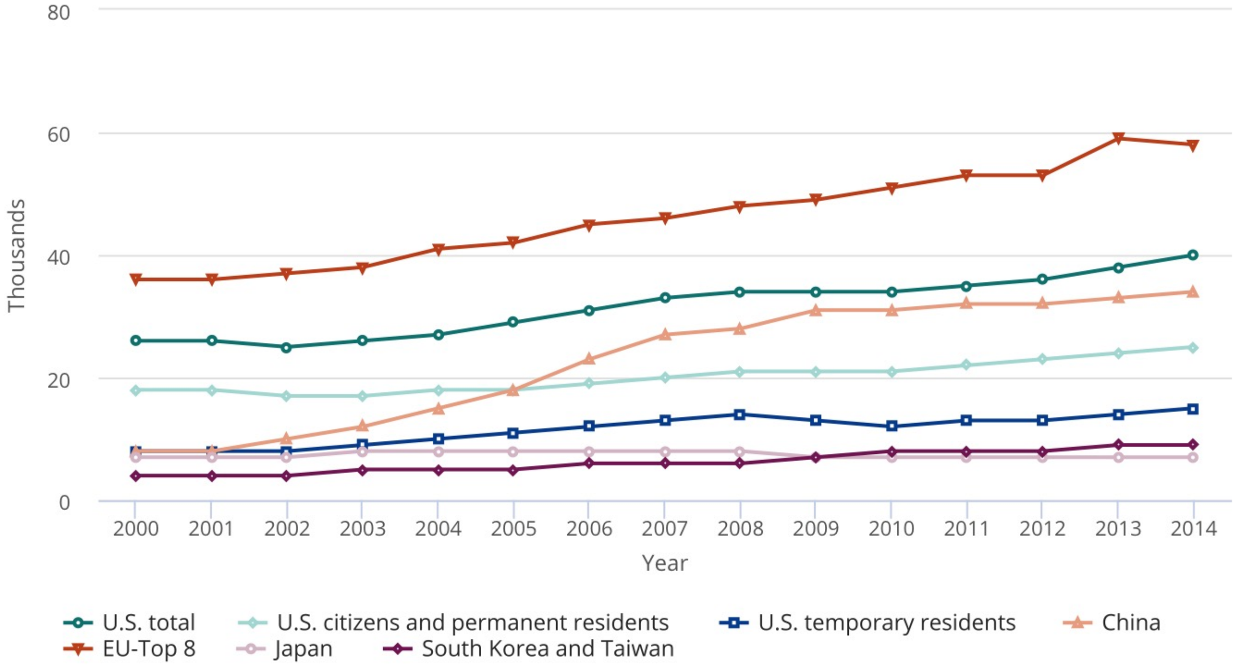
Upon superficial inspection, the modern scientific research and development system seems to be operating very successfully [AAAS2 2018; NSF 2018; Nelson 1993; OECD 2018]:

- Each year, over 750,000 bachelor's degrees in science and engineering fields are awarded in the United States, and over 4 million worldwide, as shown in Fig. 1.1(a).
- Likewise, each year over 40,000 science and engineering doctoral degrees are awarded in the United States, and over 200,000 worldwide, as illustrated in Fig. 1.1(b).
- Some of those degree recipients go into other work, but many join the pool of people who are currently doing scientific research, which is over 1.3 million researchers in the United States and growing, and over 7 million researchers worldwide and growing, as graphed in Fig. 1.2(a).
- Each year, those researchers receive an estimated total (both public and private funding) of \$500 billion in the United States and over \$1.7 trillion worldwide for research and development (R&D), as shown in Fig. 1.2(b).
- With that funding, each year they produce over 2 million new journal articles worldwide, as illustrated in Fig. 1.3(a).
- Also with that funding, each year they produce over 3.3 million new patent applications worldwide, as graphed in Fig. 1.3(b).
- Along the way, modern researchers have produced recent popular products such as smartphones, a wide variety of internet sites for social networking and sales, computer-generated visual effects, new computer games, 3D printers, and pharmaceuticals ranging from Viagra to opioids.

Yet upon closer examination, the modern research system appears to have serious problems, as suggested by several different lines of evidence that are considered in the following sections.



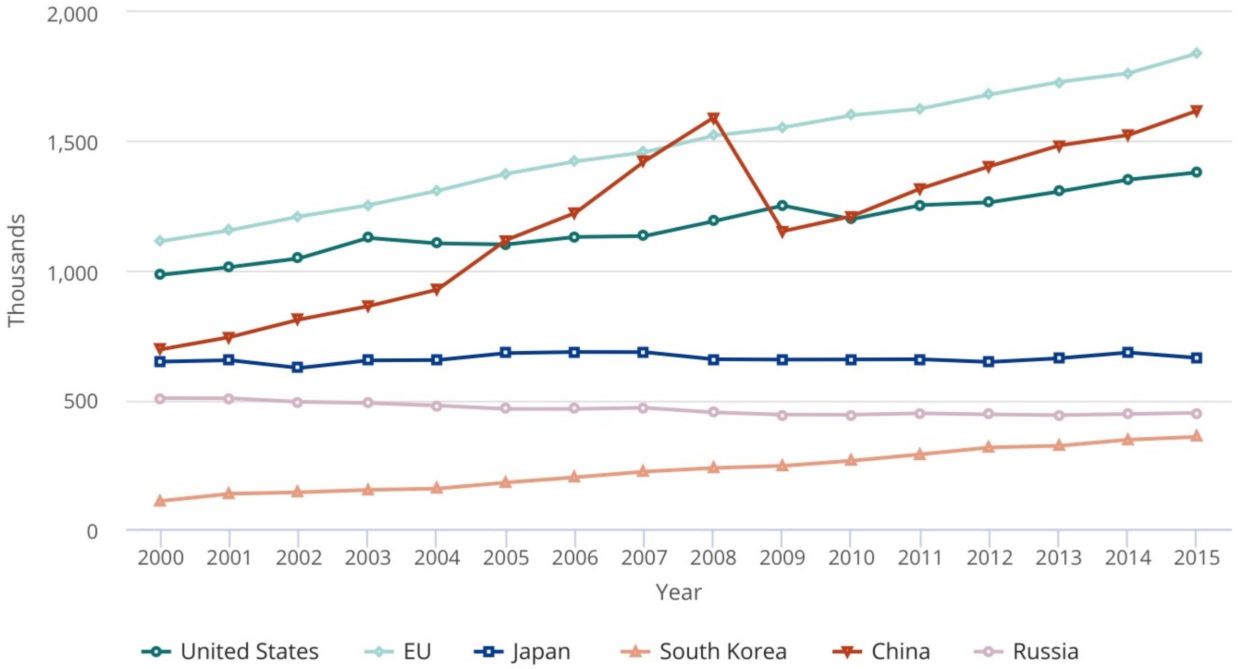
(a) Bachelor's degrees awarded in science and engineering fields in various countries



(b) Doctoral degrees awarded in science and engineering fields in various countries

Figure 1.1: Number of (a) bachelor's degrees and (b) doctoral degrees awarded in science and engineering fields in various countries each year; note that many countries (such as India) are not included in the graphs [https://www.nsf.gov/statistics/2018/nsb20181/figures].

(a) Estimated number of researchers in various countries



(b) Total R&D spending of various countries in purchasing power parity (PPP) dollars

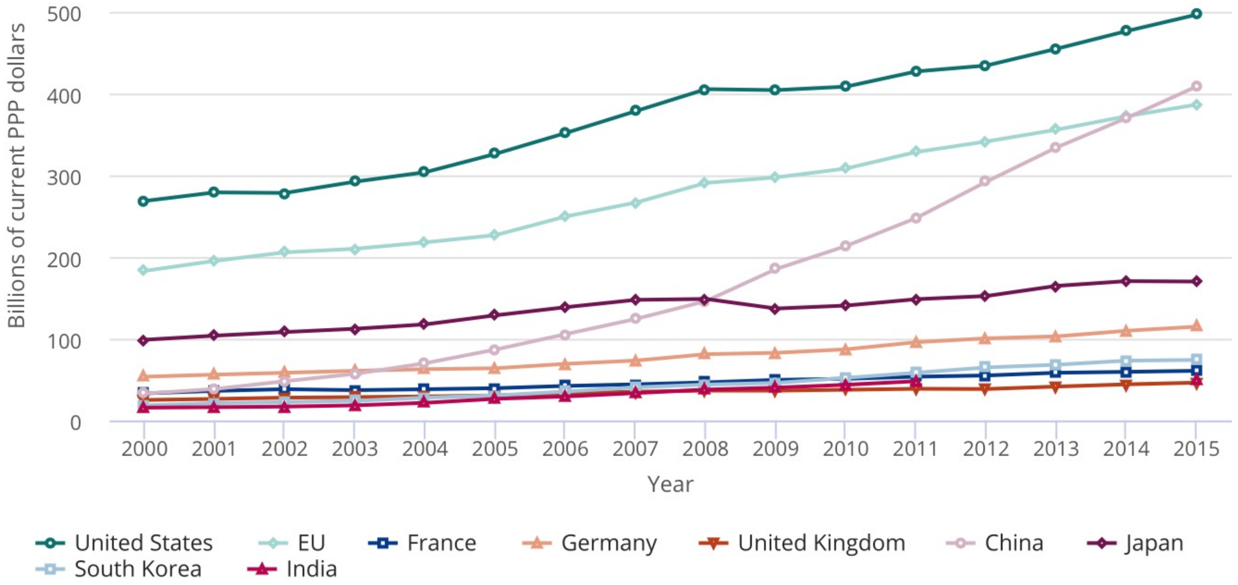


Figure 1.2: Research system sizes as measured by (a) estimated number of researchers in various countries, and (b) total R&D spending of various countries in purchasing power parity (PPP) dollars [https://www.nsf.gov/statistics/2018/nsb20181/figures]. (In the upper graph, the apparent 2008–2009 drop in researchers in China is just an artifact of a change in how Chinese researchers were counted before vs. after that time; by either method of counting, the number of Chinese researchers steadily increased throughout the time period of the graph.)

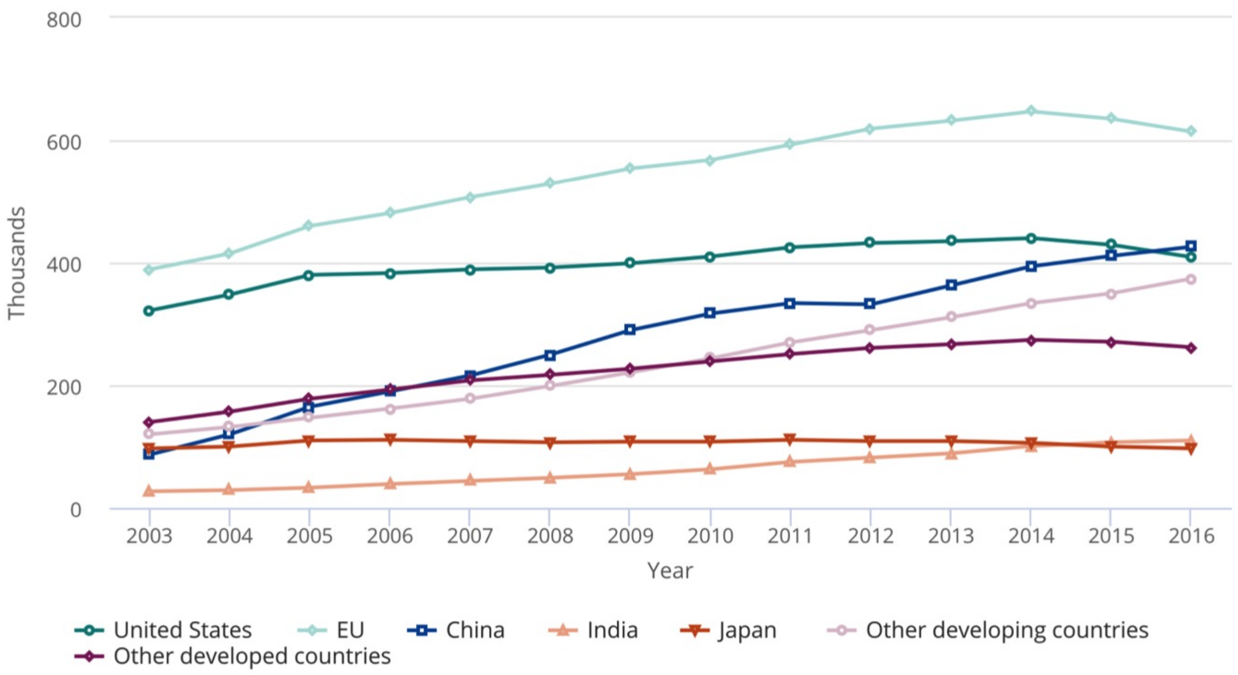
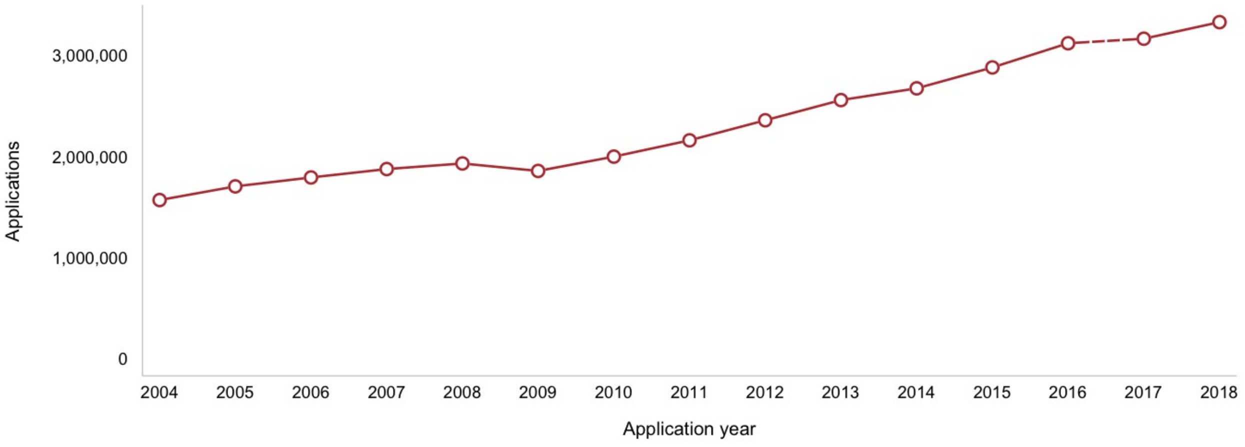


(a) Science and engineering articles by various countries



(b) Total patent applications filed worldwide

Figure 1.3: Annual production of (a) science and engineering articles by various countries, and (b) total patent applications filed worldwide [https://www.nsf.gov/statistics/2018/nsb20181/figures; https://www.wipo.int/edocs/pubdocs/en/wipo_pub_941_2019.pdf].

1.1.1 Problems from Everyday Experience

At least in the developed world, most of the technologies encountered in people's daily lives have not changed much over the last half century. We still travel around in very similar automobiles and jet planes, spend too much time in front of color video screens (even if they are nicer now and come in more sizes), and struggle to cure cancer. Only a few visible technologies have changed significantly over the last 50 years: virtually everyone has a phone in their pocket instead of on their desk, and anyone can use a computer instead of just workers in large offices. In contrast, there were large numbers of completely transformative technological changes over any 50-year span during the nineteenth century and for most of the twentieth century: electric lighting and appliances, indoor plumbing and air-conditioning, trains and automobiles, vaccines and antibiotics, jets and helicopters, transistors and lasers, nuclear power and weapons, submarines on the ocean floor and astronauts on the moon. By the standards of everyday experience, in absolute terms the rate of modern scientific innovation seems much lower now than it had been decades ago, despite the record-breaking amounts of funding, people, and papers involved in the modern system. Certainly the rate of revolutionary innovation per dollar or per person working in the system appears to be far lower now than in the past.

The longtime science journalist Michael Hanlon summed up this apparent decline [Hanlon 2014]:

> Yet there once was an age when speculation matched reality. It spluttered to a halt more than 40 years ago. Most of what has happened since has been merely incremental improvements upon what came before. That true age of innovation—I'll call it the Golden Quarter—ran from approximately 1945 to 1971. Just about everything that defines the modern world either came about, or had its seeds sown, during this time. The Pill. Electronics. Computers and the birth of the internet. Nuclear power. Television. Antibiotics. Space travel... The Green Revolution in agriculture... Mass aviation... Cheap, reliable and safe automobiles. High-speed trains. We put a man on the Moon, sent a probe to Mars, beat smallpox and discovered the double-spiral key of life. The Golden Quarter was a unique period of less than a single human generation, a time when innovation appeared to be running on a mix of dragster fuel and dilithium crystals.
>
> Today, progress is defined almost entirely by consumer-driven, often banal improvements in information technology. The US economist Tyler Cowen, in his essay *The Great Stagnation* (2011), argues that, in the US at least, a technological plateau has been reached. Sure, our phones are great, but that's not the same as being able to fly across the Atlantic in eight hours or eliminating smallpox. As the US technologist Peter Thiel once put it: "We wanted flying cars, we got 140 characters."
>
> But it could have been so much better. If the pace of change had continued, we could be living in a world where Alzheimer's was treatable, where clean nuclear power had ended the threat of climate change, where the brilliance of genetics was used to bring the benefits of cheap and healthy food to the bottom billion, and where cancer really was on the back foot. Forget colonies on the Moon; if the Golden Quarter had become the Golden Century, the battery in your magic smartphone might even last more than a day.

As illustrated by additional data in the next section, Hanlon's diagnosis of an innovation decline appears to be correct. However, like most people in the modern world, he incorrectly perceived most modern innovations as having come from the United States during the first few decades after World War II. As this book shows, the specific innovations that he cited, and the highly creative scientists and engineers who produced them, can actually be traced to a different time and place.

1.1.2 Problems from Published Analyses

Using more quantitative and detailed methods of analysis, various researchers have studied the rate of production of major scientific and technological innovations and published their conclusions that the rate has indeed been declining over the last several decades. A few examples are shown in Figs. 1.4–1.5.

Stanford researchers Nicholas Bloom, Charles I. Jones, John Van Reenen, and Michael Webb conducted a detailed study [Bloom et al. 2020]. They found that between 1930 and 2000, the number of researchers in the United States increased by a factor of 23, whereas the U.S. economic growth rate due to research innovation fell by a factor of approximately 1.78, so the productive innovation rate per researcher fell by a factor of 41. (See Fig. 1.4 top.) In other words, according to this study, the average researcher in 1930 produced 41 times more innovation than the average researcher in 2000. The same study found similar declines in innovation productivity as measured in specific fields such as medicine, electronics, and agriculture:

> [W]e proceed to measure research productivity in many different contexts. Our robust finding is that research productivity is falling sharply everywhere we look. Taking the US aggregate number as representative, research productivity falls in half every 13 years: ideas are getting harder and harder to find. Put differently, just to sustain constant growth in GDP per person, the United States must double the amount of research effort every 13 years to offset the increased difficulty of finding new ideas. [...] A first-order fact of growth empirics is that research productivity is falling sharply. [...]
>
> Akcigit and Kerr (2018) suggests that "follow on" innovations may be smaller than original innovations and provide evidence that research productivity declines with firm size. Incumbent firms may shift to "defensive" R&D to protect their market position, and this could cause research productivity to decline; Dinopoulos and Syropoulos (2007) provides a model along these lines. Or perhaps declines in basic research spending, potentially related to the US decline in publicly-funded research as a share of GDP, have negatively impacted overall research productivity. Clearly this would have important policy implications.

U.S. Navy physicist Jonathan Huebner published an earlier analysis of the number of revolutionary innovations per person per year. (See Fig. 1.4 middle.) Although his data sources and methods of analysis were significantly different than those of Bloom et al., Huebner also found a steep decline in the number of innovations per person per year over the last several decades [Huebner 2005]:

> There is a general consensus that technology is advancing exponentially, and that this advance will continue into the distant future. The basic assumption behind this view is that either there is no limit to technological advance, or if there is a limit, then we are far from reaching it. The history of technological innovation from the end of the Dark Ages to the present time is examined, and evidence is provided that we are closer to a technological limit than many people realize.

> There are two different technological limits. The first limit is a physical one, due to the laws of physics, such as the impossibility of building a perpetual motion machine. The second limit is economic; it is physically possible to dig a canal from the Pacific Ocean to the Atlantic Ocean across the continental United States, but it is not economically feasible. This paper addresses the economic limit, as we will reach this limit before the physical limit. [...]
>
> In conclusion, the evidence presented indicates that the rate of innovation reached a peak over a hundred years ago and is now in decline. This decline is most likely due to an economic limit of technology or a limit of the human brain that we are approaching. We are now approximately 85% of the way to this limit, and the pace of technological development will diminish with each passing year.

Molecular geneticist Jan Vijg analyzed the historical innovation rate too [Vijg 2011]. (See Fig. 1.4 bottom.) Whereas Bloom et al. and Huebner presented their results as declines in the number of innovations per person per year, Vijg simply plotted the total number of innovations per year (not also per person). According to Vijg, that total innovation rate has fallen markedly for several decades, even though the population has greatly increased during that time. Thus Vijg's statement about innovation decline is even stronger than those by Bloom et al. and Huebner. Vijg explained [Vijg 2011, p. 31]:

> Of the more than 300 macro-inventions listed in the table, fewer than 50 were made before 500 BC, with over 100 only from the last 100 years. What this tells us is that inventions accumulated faster in more recent times, which confirms the expectations of most futurologists and is undoubtedly something most of us would intuitively expect. Sometimes intuition is right and when plotting the number of new inventions since 500 BC, we do indeed see an exponential increase[....] The same is true when plotting not the accumulated number of inventions, but the number of new inventions per year, i.e. a measure for inventiveness [Fig. 1.4 bottom]. However, from this graph we can also see the beginning of a decline around 1970 with no sign of a restoration yet[....]

In the most extensive study yet, management professors Michael Park, Erin Leahey, and Russell Funk statistically analyzed millions of journal articles and patents. (See Fig. 1.5.) They demonstrated a pronounced decline over recent decades in the average amount of innovation (the CD_5 or Coefficient of Disruption 5 years after publication) per paper or per patent [Park et al. 2023]:

> Recent decades have witnessed exponential growth in the volume of new scientific and technological knowledge, thereby creating conditions that should be ripe for major advances. Yet contrary to this view, studies suggest that progress is slowing in several major fields. Here, we analyse these claims at scale across six decades, using data on 45 million papers and 3.9 million patents from six large-scale datasets, together with a new quantitative metric—the CD index—that characterizes how papers and patents change networks of citations in science and technology. We find that papers and patents are increasingly less likely to break with the past in ways that push science and technology in new directions. This pattern holds universally across fields and is robust across multiple different citation- and text-based metrics.

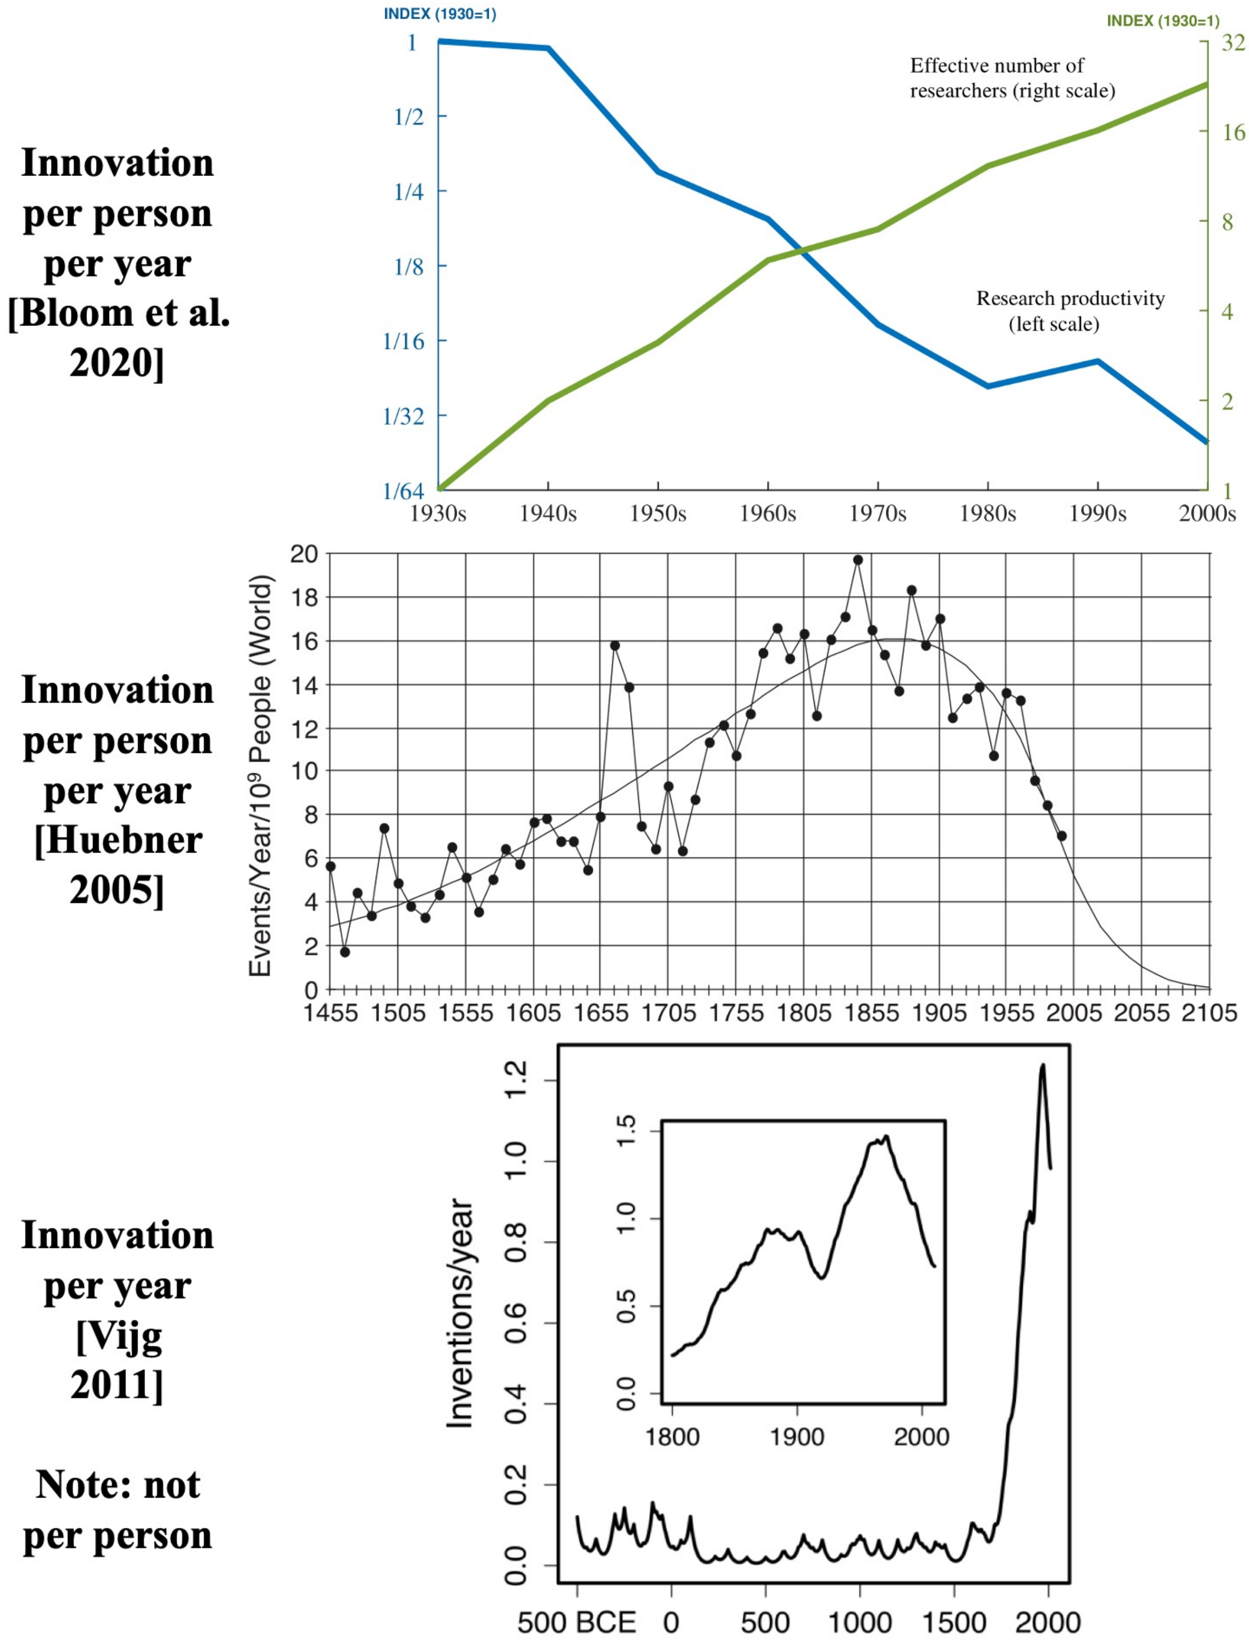


Figure 1.4: Examples of independent analyses indicating a modern decline in number of new scientific innovations per person per year [Bloom et al. 2020; Huebner 2005; Vijg 2011].

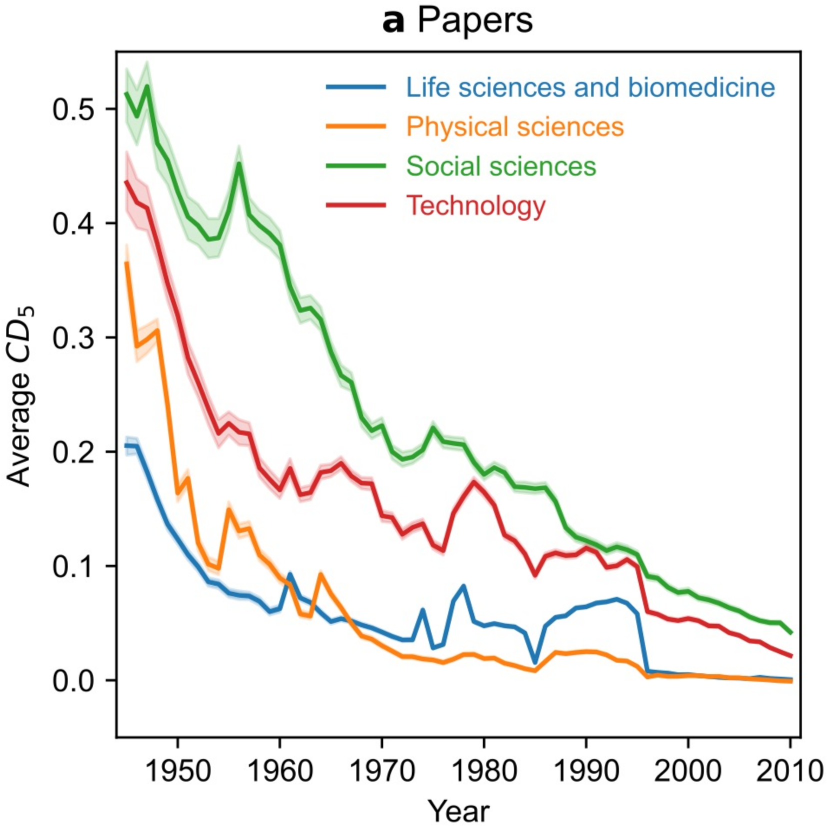
Innovation per journal article [Park et al. 2023]



Innovation per patent [Park et al. 2023]

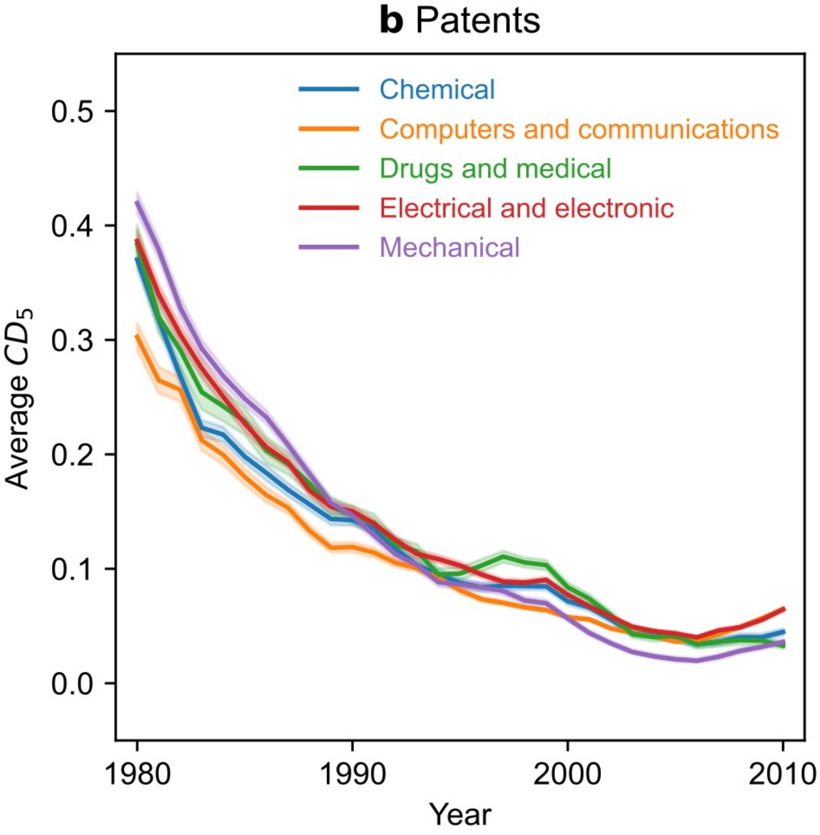


Figure 1.5: Further examples of independent analyses indicating a modern decline in the amount of innovation (the CD_5 or Coefficient of Disruption 5 years after publication) per journal article or per patent [Park et al. 2023].

These four analyses showing a significant decline in the number of revolutionary innovations per person per year, or even the total number of revolutionary innovations per year, are not isolated studies or outlier results. Some other analysts warning of the recent innovation decline include:

- Marc Andreessen, a venture capitalist [Andreessen 2020]
- Ashish Arora, Sharon Belenzon, and Andrea Patacconi, economists [Arora et al. 2015, 2019]
- Robert Atkinson, an economist [Atkinson 2014a, 2014b; Foote and Atkinson 2019]
- Professor Jeremy Baumberg, a nanotechnology researcher at Cambridge University [Baumberg 2018]
- Professors Jay Bhattacharya and Mikko Packalen [Bhattacharya and Packalen 2020]
- Professors Kevin J. Boudreau, Eva C. Guinan, Karim R. Lakhani, and Christoph Riedl [Boudreau et al. 2016]
- Donald Braben, a retired British Petroleum research manager [Braben 1994, 2004, 2008, 2014]
- Bill Buxton, a *Bloomberg Businessweek* writer [Buxton 2008]
- Nicholas Carr, a *Wall Street Journal* writer and book author [Carr 2012, 2015]
- ETH Zürich professors Peter Cauwels and Didier Sornette [Cauwels and Sornette 2020]
- Professors Johan S. G. Chu and James A. Evans [Chu and Evans 2021]
- Patrick Collison and Michael Nielsen, Silicon Valley venture capitalists [Collison and Nielsen 2018; Collison and Cowen 2019; Noah Smith 2020]
- Tyler Cowen, an economist [Collison and Cowen 2019; Cowen 2011; Cowen and Southwood 2019]
- Steve Denning, a *Forbes* writer [Denning 2013]
- Ross Douthat, a *New York Times* columnist [Douthat 2020]
- Elizabeth Dzeng, a scholar at Cambridge University [Dzeng 2014]
- Judy Estrin, a veteran Silicon Valley entrepreneur [Estrin 2008; NYT 2008-09-01, p. C4]
- Justin Fox, a former *Harvard Business Review* editorial director [Fox 2012]

- Robert Gordon, an economist [Gordon 2000, 2012, 2016]
- Lynn Gref, a retired NASA and Defense Department manager [Gref 2010]
- Jonathan Gruber and Simon Johnson, MIT economists [Gruber and Johnson 2019]
- John Horgan, a science journalist [Horgan 2015]
- Greg Ip, chief economics commentator for the *Wall Street Journal* [Ip 2016]
- Walter Isaacson, historian of science [Isaacson 2019]
- Leslie Kwoh, a *Wall Street Journal* writer [Kwoh 2012]
- Martín López-Corredoira, an astrophysicist [López-Corredoira 2013]
- Michael Mandel, a *Bloomberg Businessweek* writer [Mandel 2009]
- Chris Matthews, a *Fortune* magazine writer [Matthews 2015]
- Derek de Solla Price, an historian of science [Price 1986]
- Simon Ramo, a retired TRW cofounder [Ramo 1980a, 1983, 1988]
- Richard Rosenbloom, a Harvard Business School professor [Rosenbloom and Spencer 1996]
- Daniel Sarewitz, an Arizona State University science policy professor [Sarewitz 2016]
- William Spencer, a former Sematech CEO [Rosenbloom and Spencer 1996]
- Neal Stephenson, a science fiction author [Stephenson 2011]
- Peter Thiel, a technology investor [Thiel 2011, 2016, 2023]
- Derek Thompson, a journalist at *The Atlantic* [Derek Thompson 2021]
- Dietrich Vollrath, a University of Houston professor [Vollrath 2020]
- A high-ranking panel from the American Academy of Arts & Sciences [AAAS1 2014]
- A high-ranking panel from MIT [MIT 2015]
- A high-ranking panel from the U.S. National Academy of Sciences [NAS 2007, 2010]

1.1.3 Problems with Modern Academic Research

While universities have produced innovators, discoveries, and inventions for centuries, many observers have reported widespread problems with the modern academic system.[1] Examples include:

(a) Professors at many universities are generally evaluated primarily or exclusively for research, so they tend to neglect teaching. Professors who are deemed to invest too much effort in teaching may even be denied tenure or otherwise punished, while other professors often delegate teaching to poorly paid adjunct professors or graduate students.

(b) The modern academic system seems to be extremely focused on publishing as many papers as possible, even if they are highly repetitive of previous papers by the same researchers, do little to actually advance their field, and often are of dubious quality (or even plagiarized or faked entirely).[2] Researchers openly talk about maximizing the number of "minimum publishable units." Academics are so judged by their continuous high production rate of papers that they cannot really afford to get negative results. For that reason, they tend to pursue experiments (1) with a readily predictable and immediate payoff, (2) with insufficient optimization for repeatability, (3) with very little risk or innovation, and (4) preferably without focusing on truly practical applications that would take much longer to perfect. Likewise, academics usually cannot afford the time to publish any negative results if they do happen to get them (which would be very helpful to warn others of dead ends or misconceptions). The result appears to be an exponentially increasing deluge of repetitious, minimally innovative, or even spurious papers.

(c) Although it is considered to be by far the most important product of the system, this output of papers seems to end up largely unread and unutilized because (1) the number of papers is so incomprehensibly vast, (2) the papers are inaccessible to most of the world due to exorbitant online journal paywalls or the cost or obscurity of the printed volumes in which they appear, and (3) most academic researchers are too busy frantically writing their own papers to spend much time reading, trying to replicate, or applying other researchers' papers.

(d) Instead of multidisciplinary cross-pollination or even proper perspective within a given field, modern academia seems to demand extreme microspecialization. To compound the problem, researchers in each subfield appear to continually develop more and more unnecessarily specialized vocabulary, and this "tower of Babel" effect makes it much more difficult for (1) students to learn a given field, (2) researchers in different fields to communicate or spread ideas, (3) the public to understand and appreciate the work, and (4) the work to have any impact in the real world beyond the virtually inaccessible specialized literature.

---

[1] E.g., Aitkenhead 2013; Alberts et al. 2014; Armstrong 1997; Baumberg 2018; Begley 2009; Belluz et al. 2016a, 2016b; Bhattacharya and Packalen 2020; Blumenstyk 2014; Brenner 2014; Brezis 2007; Carey 2015; Carr 2009; Childress 2019; Chu and Evans 2021; Dzeng 2014; *Economist* 2010; Farrow 2019; Feighery 2013; Frey 2003; Garner 2006; Gee 2017; Gillies 2008; Godlee et al. 1998; Horrobin 1990; Ietto-Gillies 2008; Junod 2013; Kendzior 2015; Kennefick 2009; Lin 2014; López-Corredoira 2013; Maddox 1995; Mahoney 1997; Merton 1968; O'Shaughnessy 2012; Peters and Ceci 1982; Racker 1989; Ritchie 2020; Rothwell and Martyn 2000; Sandal 2011a, 2011b, 2016; Scott 2012; Taschner 2007; Tarver 2007; Warner 2020; Ziman 1995.

[2] E.g., Begley and Ellis 2012; Buranyi 2017; Errington et al. 2021a, 2021b; Francis 2020; Schneider 2016, 2017, 2020.

(e) Universities now seem to be bottomless pits for tuition, research grants, donations, university-hosted conference fees, and other funding, with tuition rising far faster than inflation for many decades, university faculty and staff endlessly pursuing wealthy donors and sponsor grants full-time, untapped university endowments mounting ever higher, and an explosion of administrators, extravagant campus architectural projects, ever more expensive athletic programs and facilities, and other costs with at best a tenuous connection to actual research and education.

(f) For decades there has been an exponential multiplication of professors and postdocs who want to be professors. Although this process began as a way to build up an academic system from minimal roots, in the modern environment in which the number of positions for professors has been relatively constant for years, it now functions for all practical purposes as a pyramid or Ponzi scheme that primarily benefits those who got in earlier. Those entering the system more recently tend to work very long hours to make the whole system function, are paid quite poorly, and have very dim career prospects.

Many observers (such as those cited) have reported these problems, but the most colorful summation was provided by Mark Tarver, a former professor at the University of Leeds [Tarver 2007]:

> Teaching was not the only criterion of assessment. Research was another and, from the point of view of getting promotion, more important. Teaching being increasingly dreadful, research was both an escape ladder away from the coal face and a means of securing a raise. The mandarins in charge of education decreed that research was to be assessed, and that meant counting things. Quite what things and how wasn't too clear, but the general answer was that the more you wrote, the better you were. So lecturers began scribbling with the frenetic intensity of battery hens on overtime, producing paper after paper, challenging increasingly harassed librarians to find the space for them. New journals and conferences blossomed and conference hopping became a means to self-promotion. Little matter if your effort was read only by you and your mates. It was there and it counted.
>
> Today this ideology is totally dominant all over the world, including North America. You can routinely find lecturers with more than a hundred published papers and you marvel at these paradigms of human creativity. These are people, you think, who are fit to challenge Mozart who wrote a hundred pieces or more of music. And then you get puzzled that, in this modern world, there should be so many Mozarts—almost one for every department.
>
> The more prosaic truth emerges when you scan the titles of these epics. First, the author rarely appears alone, sharing space with two or three others. Often the collaborators are Ph.D. students who are routinely doing most of the spade work on some low grant in the hope of climbing the greasy pole. Dividing the number of titles by the author's actual contribution probably reduces those hundred papers to twenty-five. Then looking at the titles themselves, you'll see that many of the titles bear a striking resemblance to each other. "Adaptive Mesh Analysis" reads one and "An Adaptive Algorithm for Mesh Analysis" reads another. Dividing the total remaining by the average number of repetitions halves the list again. Mozart disappears before your very eyes.

> But the last criterion is often the hardest. Is the paper important? Is it something people will look back on and say "That was a landmark." Applying this last test requires historical hindsight—not an easy thing. But when it is applied, very often the list of one hundred papers disappears altogether. Placed under the heat of forensic investigation the list finally evaporates and what you are left with is the empty set.
>
> And this, really, is not a great surprise, because landmark papers in any discipline are few and far between. Mozarts are rare and to be valued, but the counterfeit academic Mozarts are common and a contributory cause to global warming and deforestation.

[For the history of these trends, see for example: Buranyi 2017; Francis 2020.]

Because of all of the above problems, and because it is now more efficient and far cheaper for students to do much of their academic coursework online, utilizing the best recorded lectures and curriculum materials, it is currently unclear how universities should or will change in the coming decades.

1.1.4 Problems with Modern Corporate Research

Decades ago, corporate research programs made sizeable investments in very innovative, longer-term research and development projects, ultimately leading to products ranging from revolutionary microelectronics to whole new classes of pharmaceuticals. Unfortunately, corporate research (even including start-up companies and venture capitalists) now appears to be hobbled by several widespread problems, such as:[3]

(a) With top management and investors seemingly focused only on tomorrow's stock prices and next year's products, companies are generally only interested in developing very near-term, very low-risk (non-innovative) products.

(b) There appears to be a strong financial incentive for companies to take whatever amount of innovation does exist in their R&D pipeline and spread that innovation out for as many years as possible over a long succession of slightly improved products, in order to ensure planned obsolescence of each product and profitable sales of the next version of the product. There seems to be a strong disincentive to release as much innovation as possible as quickly as possible, which would spur the need for much more extensive and accelerated innovative research programs to refill the pipeline with future products.

(c) Research and development for any period of time is apparently viewed as an immediate financial loss for the company, not an investment in the company's future, and scaled back or entirely replaced with the hope of finding some other company's research that can be bought out or simply imitated. It is presumably much more lucrative to wait for someone else to invest in developing an innovative product, then just copy that product and try to capture as much of the market share as possible.

---

[3] E.g., Arora 2015; Buxton 2008; Denning 2013, 2014; Hsueh 2015; Kwoh 2012; Lyons 2016, 2018; Matthews 2015; Mittra 2009; O'Neill 2012; Pearlstein 2018; Ramo 1980a, 1983, 1988; Rosenbloom and Spencer 1996; Slywotzky 2009; Terkel 2011; NYT 2011-05-02, 2015-05-20, 2016-06-30.

(d) Companies tend to be very unstable, with an endless series of mergers, acquisitions, or internal reorganizations that can completely redirect any research and development priorities on an almost annual basis.

(e) Profits for top management and investors seem to grow ever larger while rewards and working conditions for the actual research and development employees have stagnated at low levels or even worsened in recent years. Upper management tends to view the workers as disposable, interchangeable cogs in the machine that can be frequently and easily replaced, not skilled experts whose abilities should be cultivated, allowed to reach their maximum potential, and rewarded with and for longtime service.

Simon Ramo, cofounder of TRW, saw these problems arise in the 1970s [Ramo 1980a, pp. 55–56]:

> New technology is by its nature speculative. Risk taking is part of the task of management in the private sector but in periods of diminishing rewards smaller risks will be favored. This means priority will go to sticking to existing technology and making only small changes in techniques of manufacture and in the products themselves. Managers of R&D in American corporations are now reporting a heavy shift in emphasis to short-term programs either to produce safe, non-speculative, incremental improvements or else to learn how to comply with new government environmental and safety regulations. Basic research has been disappearing from private U.S. industry. Another factor is that principal executives, while not disinterested in long-term investments that may enhance the company's position after they have retired, have a natural desire to see results while they are still in the driver's seat. They are increasingly less motivated to make risky, long-term investments as their concern grows about U.S. economic-political stability over the lengthening period required to see a speculative investment through to successful completion. [...]
>
> After World War II there was a burgeoning in the United States of new technological industries: computers, agricultural technology, instant copiers, telecommunications, jet transport, semiconductors, nuclear reactors, spacecraft, fast foods, new chemicals and pharmaceuticals, and many more. Some of these product areas are now approaching maturity. We need new ideas and enterprises as well as continued enhancement and expansion of the fields in which we have a strong position.

The problems succinctly diagnosed by Ramo in 1980 have only worsened in the several decades since then, as shown by the references about corporate research cited above.

As with Michael Hanlon (see p. 42), most or all of the innovations that Ramo attributed to the United States during the first few decades after World War II can actually be traced to a different time and place, as this book shows.

1.1.5 Problems with Modern Government Research

Although government-run or government-funded laboratories played major roles in developing revolutionary innovations (nuclear technology, radar, space flight, guidance systems, etc.) many decades ago, they now seem to be mired in a number of problems.[4] In general the problems include:

(a) Each lab appears to be strongly focused on some core technology that was very innovative roughly three-quarters of a century ago when the lab was founded, but that is now very mature and for which government funding is steadily declining.

(b) Because of their previously reliable government funding and potentially dangerous core technologies, government labs tended to develop very risk-averse management cultures in which it is generally much safer politically to do nothing than to support any progress or change.

(c) Any new work at government labs seems to be highly constrained by a wide variety of internal and external regulations that have greatly increased in number and severity over the last 75 or so years.

(d) As funding for government labs has declined in recent years, not only have their research staff sizes decreased, but the surviving staff members have had to devote larger and larger fractions of their time to pursuing outside resources instead of actually conducting research. In many cases, the staff members spend much of their time writing proposals to try to obtain funding from outside sponsors. In other cases, the surviving staff are no longer allowed to conduct their own research, but rather must spend their time selecting and managing outside contractors to do the research.

(e) In cases where government labs have attempted to reform their structures and their areas of research, those reforms often mimic some of the worst practices of modern industry, for example either by focusing on very short-term, non-innovative, low-risk work or else by investing in a rapid succession of poorly thought-out “get rich quick” schemes.

(f) For all of the preceding reasons, government labs often have great difficulty attracting and retaining talented scientific professionals, and may instead accumulate mediocre personnel to fill out available positions, with some of those mediocre personnel ultimately rising to management positions at all levels as managerial openings become available over time.

---

[4] E.g., Alvarez 2014; GAO 2016; Gref 2010; Harris and Benincasa 2014; King 2011; Kramer 2016; Lucibella and Levine 2010; Mann 2011; McCurdy 1993; Nesbit 2016; Odenwald 1995; Sisk 2015; Steinbock 2015; Trento and Trento 1987; Trigaux 2015; Young 2015a, 2015b; NYT 2011-01-23, 2011-09-11.

Howard McCurdy, professor of public affairs at American University, summarized these problems in his detailed analysis of NASA's management history [McCurdy 1993, pp. 1–2]:

> The people who ran the National Aeronautics and Space Administration (NASA) when the agency was young developed methods of doing business that allowed them to carry out extraordinarily difficult tasks. NASA civil servants discovered ways to circumvent bureaucratic restrictions and avoid failure when it threatened to occur. They adopted an organizational philosophy suited to the scientific and technological missions they were asked to perform. NASA acquired a reputation as a high-performance government organization.
>
> As NASA grew older, it changed. Beliefs about how the agency should be run persisted, but no longer did those beliefs elicit the behavior that characterized the early years. NASA grew more bureaucratic. It became more concerned with maintaining its survival. In the eyes of some people, its performance declined. The onset of maturity changed NASA. The agency that embarked upon the 1990s was a different one than the NASA that sent astronauts to the Moon. The NASA story helps reveal forces that work to mollify the capabilities of high-performance organizations in the public sector. Unlike business firms, whose fundamental outlooks tend to persist over long periods of time, NASA's organizational culture blossomed and lost strength within just thirty years. The NASA experience suggests that high-performance cultures within the public sector are inherently unstable, given the conditions with which they must deal.

Thus government-run or government-funded laboratories fell into increasing dysfunction over the course of several decades, just as the academic and corporate research sectors did.

1.2 Scientific Innovation in the Earlier German-Speaking World

Trying to imagine completely new methods of improving the innovation system would be rather challenging (though not impossible), and any new methods might have inadequacies or even major adverse consequences that would not be discovered until they were tested in practice. As a more tractable alternative, studying the conditions that facilitated the major successes of earlier scientists and engineers in history can offer road-tested insights into how to maximize the productivity of modern researchers. Although inventions and discoveries have been made throughout the world and throughout history, high concentrations of major innovations within a given place and time should indicate especially conducive conditions for cultivating innovators and innovations.

1.2.1 Motivation for Studying the Earlier German-Speaking World

One of the highest concentrations (and arguably the highest concentration) of revolutionary discoveries and inventions came from scientists and engineers who were trained in the predominantly German-speaking central European research world in the nineteenth and early twentieth centuries. For the purposes of this study, that world is defined as containing German, Austrian, and Swiss researchers, eastern European and other researchers who were educated and/or worked in the German-speaking world, and scientists and engineers in the closely coupled Dutch research system. (Some historians of science have previously classified the Dutch system as part of the greater German-speaking scientific world [e.g., Laurie Brown et al. 1995, p. 17].) Figure 1.6 presents a map of Europe in 1914 to help visualize the relevant geographical areas.

This book focuses on scientists and engineers who received some or all of their training in that world between approximately 1800, when the German-speaking scientific world first began to take recognizable form, and 1945, when that world was essentially destroyed and then subsequently slowly rebuilt. For completeness, this book also includes all the accomplishments of those who were educated before 1945 but continued to make significant contributions after 1945.

As shown in Table 1.1, of the 99 people who received Nobel Prizes in Physics, Chemistry, and Physiology or Medicine through 1932, or prior to the Third Reich and all the problems it caused, half (49) were trained in the German-speaking research world. The other Nobel laureates were divided among a number of other research systems, including the United Kingdom, the United States, France, Sweden, Italy, etc., so the German-speaking world had by far the largest share.

Table 1.1: Prior to the Third Reich (1901–1932), 99 scientists won Nobel Prizes in Physics, Chemistry, and Physiology or Medicine. Of those scientists, 49 were trained in the German-speaking world. That figure includes **38 native German speakers (German, Austro-Hungarian, or Swiss), 7 Dutch scientists, and 4 others who were educated in the German world.** Marie Curie won two Nobel Prizes in the table, and prizes were not awarded in years with dashes.

Highly innovative scientists and engineers who were educated in that German-speaking world prior to 1945 (**creators**, as they are called throughout this book) produced a huge number of revolutionary discoveries and inventions (**creations**) that have shaped the modern world:

- Biomedical advances from genetics to antibiotics
- Chemical breakthroughs from color film to synthetic rubber
- Discoveries about the universe from continental drift to stellar distances
- Revolutionary physics from relativity to quantum mechanics
- Electrical inventions from semiconductors to computers
- Mechanical systems from automobiles to submarines
- Nuclear reactions and applications from fission to fusion
- Aerospace vehicles from jet planes to moon rockets

Almost all of the inventions cited by Hanlon (p. 42) and Ramo (p. 52) as examples of post-1945 U.S. innovation actually originated from pre-1945 German-speaking creators.

A wide range of scientific experts from outside the early German-speaking research world and after its downfall have testified about its scientific success. For example, Sir Brian Pippard from the Cavendish Laboratory of the University of Cambridge wrote [Laurie Brown et al. 1995, p. 7]:

> It cannot be doubted that in physics, as in nearly every branch of scholarship, Germany at this time [early twentieth century[5]] led the world. The universities and their researchers were highly esteemed by their own people, their learned journals were eagerly followed everywhere, and there was an abundance of local societies to meet the needs of amateurs.

---

[5] Wherever I insert my own editorial comments into quoted text, I put my comments in square brackets and in blue to make them clearly distinguishable.

John Cornwell, another British scholar from the University of Cambridge, similarly observed [Cornwell 2003, p. 7]:

> By the end of the first decade of the twentieth century, Germany had become the international Mecca of science. Researchers, basic and applied, flocked to German universities from all over the world; learned German to read the leading science journals and to participate in conferences and seminars.

As an example of an American perspective, David Hounshell, a Carnegie Mellon University professor and historian of science, wrote [Rosenbloom and Spencer 1996, pp. 19–20]:

> During the last third of the nineteenth century and the first decade and a half of the twentieth century, a preponderance of U.S. physicists and chemists earned graduate degrees in Germany. These scientists not only observed a different system of graduate education in German universities but also witnessed the evolution of a nationwide system of scientific research and industrial-academic relations that had begun after German unification in 1871. By the beginning of World War I, Germany possessed the world's most complex and advanced research system, comprised of university research programs, government- and industry-sponsored research institutes, and industrial R&D programs. These components were linked by research scientists committed to advancing science and, as necessary to this goal, technology and industry.

Despite the deleterious impact of two World Wars and the intervening economic Depression on the German-speaking world, U.S. Army Air Forces General Curtis LeMay was so impressed by the scientific innovations the United States found in German-speaking areas in 1945 that he wrote [LeMay 1946, p. 17]:

> At Wright Field, O[hio]., German scientists are now assisting American scientists in translating great masses of captured German scientific documents. These documents reveal, as the materiel at Freeman Field indicates, the extent to which German science had out-distanced American science in basic and applied scientific research and in aircraft development. It has been estimated that the Germans were 10 to 15 years ahead of us in fundamental research.

L. B. Kilgore from the U.S. Technical Industrial Intelligence Division (TIID) confirmed the very high level of the German-language scientific achievements found by the United States after the wars; in fact, he admitted that their quantity and quality were almost beyond description [L. B. Kilgore, Proposal for a Compendium of German War Time Technology, Draft No. 2, 10 January 1947, NARA RG 40, Entry UD-75, Box 3, Folder Inter-Office Memoranda: To and From Robert Reiss]:

> The accumulation of the technical industrial information, which has resulted from the detailed investigations of the German industry for the past two years by this office, has reached such enormous proportions that it has become difficult to inform the public of the possible benefits available to it. This accumulation of information not only represents the greatest transfer of mass intelligence ever made from one country to another, but it also represents one of the most valuable acquisitions ever made by this country.

A 1946 U.S. Senate report on the establishment of the National Science Foundation noted that even the major scientific accomplishments of the United States during World War II were directly derived from earlier German-speaking creators [NSF 1946, p. 6]:

> It should be somewhat humiliating to us to realize that the revolutionary sulfa drugs had their beginning in German research laboratories; that atom splitting was discovered in Berlin; that the basic pioneer work that has led to radio and radar and the enormous American electronic industries was that of a German professor. Penicillin came from England [where it was purified by Ernst Chain, a German refugee]; DDT from Germany and Switzerland.

Although the Soviet Union was much less vocal with its praise of the German-speaking scientific world, its actions spoke volumes. Beginning in 1945, the Soviet Union removed thousands of scientists and many hundreds of whole laboratories and factories from German-speaking territory, and historians have shown that the subsequent Soviet nuclear, aircraft, rocket, electronics, and other development programs owed a huge debt to the German-speaking scientists and scientific information.[6]

Unfortunately, the history of the German-speaking creators and their transformative creations has been greatly obscured by a combination of factors including:

- World War I and its aftermath
- World War II and its aftermath
- The Cold War and its secrecy requirements
- Language barriers
- Pervasive and long-standing cultural stereotypes of German-speaking scientists in the rest of the world (villainous as in James Bond and Indiana Jones stories, insane as in Frankenstein films and other mad scientist stories, and/or foolish and ridiculous as in *Hogan's Heroes* and *Dr. Strangelove*)

The creators who invented so much of the modern world have been largely forgotten (especially by non-German speakers), leaving the modern world less aware of key details in its history and less able to fully reproduce the research conditions that led to so many revolutionary achievements.

1.2.2 Scope and Outline of this Book

Due to the length of this book, all of the sections and appendices are designed to be as self-contained as possible (even though that necessitates some degree of overlap and redundancy among some sections). Please use this outline or the Table of Contents to find whatever section interests you the most, and jump straight to that without any shame.

Motivated by the reasons explained earlier in this chapter, this book presents an overview and analysis of the historical German-speaking scientific world. The revolutionary creators and creations that world produced are divided into eight very broad fields over the next eight chapters:

Chapter 2: Biology and medicine

Chapter 3: Chemistry and materials science

Chapter 4: Earth and space science

Chapter 5: Physics and mathematics

Chapter 6: Electrical and electromagnetic engineering

Chapter 7: Mechanical engineering

Chapter 8: Nuclear science and engineering

Chapter 9: Aerospace engineering

Before delving into those specific fields, it would be useful to lay out the general approach of Chapters 2–9:

- The main objective of these chapters is to illustrate both the vast number and the profound modern impact of creators and creations arising from the earlier German-speaking world.
- In order to make such a broad overview accessible within a finite number of pages and a limited amount of readers' time and attention, the presentation in these chapters is primarily visual using figures, with accompanying pages of relatively brief text to put the figures in their proper context and to refer interested readers to sources of much more detailed information.
- The sections throughout Chapters 2–9 are based on information from general sources[7] as well as additional information from more specialized references on individual science and engineering fields as listed in the Bibliography.
- Within each of the eight fields covered by Chapters 2–9, creators and creations are grouped into specific topics to facilitate an overview of the details. There is considerable overlap for some of the fields, topics, creators, and creations, and it would easily be possible to categorize the same material in many other ways.

---

[7] Especially ACLS 2000; Albrecht et al. 1992; Ash and Söllner 1996; Bar-Zohar 1967; Bower 1987; Bunch and Hellemans 2004; Challoner 2009; Cornwell 2003; Crim 2018; EB 1911, 2010; Gillispie 1970–1990; Gimbel 1990a; Glatt 1994; Hall 2019a; István Hargittai 2006, 2011; Linda Hunt 1991; Impey et al. 2008; Jacobsen 2014; Koertge 2007; Kurowski 1982; Lasby 1971; Lusar 1956, 1971; Medawar and Pyke 2000; Mick 2000; Murray 2003; Nachmansohn 1979; NDB 1953–2020; Neufeld 2012; Nouzille and Huwart 1999; O'Reagan 2014, 2019; Porter 1994; Charles Walker 1946; Peter Watson 2010; Weitensfelder 2009.

- German-derived creations for some topics are less studied and less well understood by modern historians than those for other topics. For a handful of especially important yet historically murky topics, evidence for German-language innovations in those areas is briefly mentioned in these chapters, then presented in much more detail in Appendices A–E.

- In order to give some context for the major German-speaking creators, each section also briefly mentions some major creators in that field who were outside the German-speaking world, how relevant information was imported into the German-speaking world from other innovation systems, and how the German-speaking creators' inventions and discoveries were exported to the rest of the world. A common theme for many of the sections is that non-German-speaking (especially French and British) scientists initially dominated a given field up to the mid-nineteenth century or so, German-speaking scientists adopted that work as a starting point and entered the field sometime during the nineteenth century, and by 1945 German-speaking scientists had contributed most of the major new innovations in that field and were far ahead of their competitors (in many cases by a decade or more).

- The coverage of fields, innovators, and innovations in Chapters 2–9 is reasonably thorough but certainly not exhaustive. Hopefully those that have been included here are at least sufficient to elucidate both the impact of the German-speaking creators and the systemic principles underlying their successes.

Chapter 10 investigates why the earlier German-speaking scientific world was able to produce so many revolutionary creators and creations even though it had far fewer researchers than the modern scientific world, far less funding, and a long string of dire political challenges. Its success is even more remarkable when one considers the fact that over the course of a century or so, the German-speaking scientific world went from being far behind to being far ahead of its competitors in so many different fields. Systemic innovation-promoting factors that are examined include the social status of science and scientists, the growth rate of research funding, some characteristics of the education system, the popularity of interdisciplinary scientific work, the style of scientific management, the employment of systems analysis, incentives due to natural resource constraints, and incentives due to economic and military rivalries with other countries.

Chapter 11 considers how the global community adopted so many creations from the earlier German-speaking world while forgetting so many of their creators. In different waves that occurred before, during, and after the Third Reich, many thousands of German-speaking scientists, hundreds of thousands of tons of documents on their innovations, and complete inventions and even the factories to produce them were transferred to the United States, the Soviet Union, the United Kingdom, France, and other countries. Along with those creators and creations, some innovation-promoting systemic approaches were also transferred from the earlier German-speaking world to other countries, where they facilitated further scientific innovation during the Cold War. Chapter 11 explores which general approaches were adopted, and how they were ultimately abandoned.

Chapter 12 focuses on what the modern scientific research system can learn from the earlier German-speaking world. Based on the perspective accumulated in Chapters 1–11, Chapter 12 offers suggestions for:

- State or national innovation systems that would like to increase their production of revolutionary research

- Individual companies, organizations, or laboratories that would like to pursue more innovative research

- Individuals who are now trying to pursue careers in innovative research in the existing state of the global system

- Scholars who would like to further study the past, present, and potential future of revolutionary scientific innovators and innovations

The appendices focus on some potentially quite advanced creations of the German-speaking world during World War II that are currently much less well understood by modern historians, and whose complexities necessitate a considerably longer treatment than could be given in Chapters 2–9:

> **Appendix A** presents archival documents that suggest that Germany had the largest and most advanced biotechnology programs in the world at that time, was developing neural interfaces to control prosthetic limbs and weapons systems, possessed a significant offensive program in biological warfare, and discovered advanced V-series nerve agents during the war.
>
> **Appendix B** gives an overview of evidence that transistors and other microelectronics innovations may have originated in the German-speaking world, and that information on those technologies may have been transferred to and exploited by Allied countries after the war.
>
> **Appendix C** presents documents that appear to show that the German-speaking world developed and tested a variety of directed-energy technologies, including particle beams, electromagnetic pulse weapons, major steps toward lasers, focused sound waves for applications ranging from ultrasound imaging to acoustic weapons, and electromagnetic railguns.
>
> **Appendix D** provides considerable evidence that Germany may have developed and even successfully tested fission bombs during the war (which would have made it the first country in world history to do so), and that it may have even had a megaton-level hydrogen bomb in an advanced stage of development when the war ended.
>
> **Appendix E** presents archival documents that appear to show that wartime Germany made considerable progress toward developing the aerospace technologies that have formed the “nuclear triad” for most of the postwar decades: intercontinental jet bombers, intercontinental ballistic missiles, and submarine-launched missiles.

Although the evidence in the appendices does not constitute conclusive proof, it should prompt further archival research to clarify the true extent of those wartime programs.

The primary motivation for this study is one of practical modern self-interest, to identify factors that might improve present and future scientific productivity. However, there is also an underlying historical obligation. The names of Marco Polo, Christopher Columbus, Neil Armstrong and Buzz Aldrin, and other pioneers are remembered by the modern world. The German-speaking scientists and engineers who played such vital roles in creating our modern world deserve to be remembered as well.

1.2.3 Disclaimers

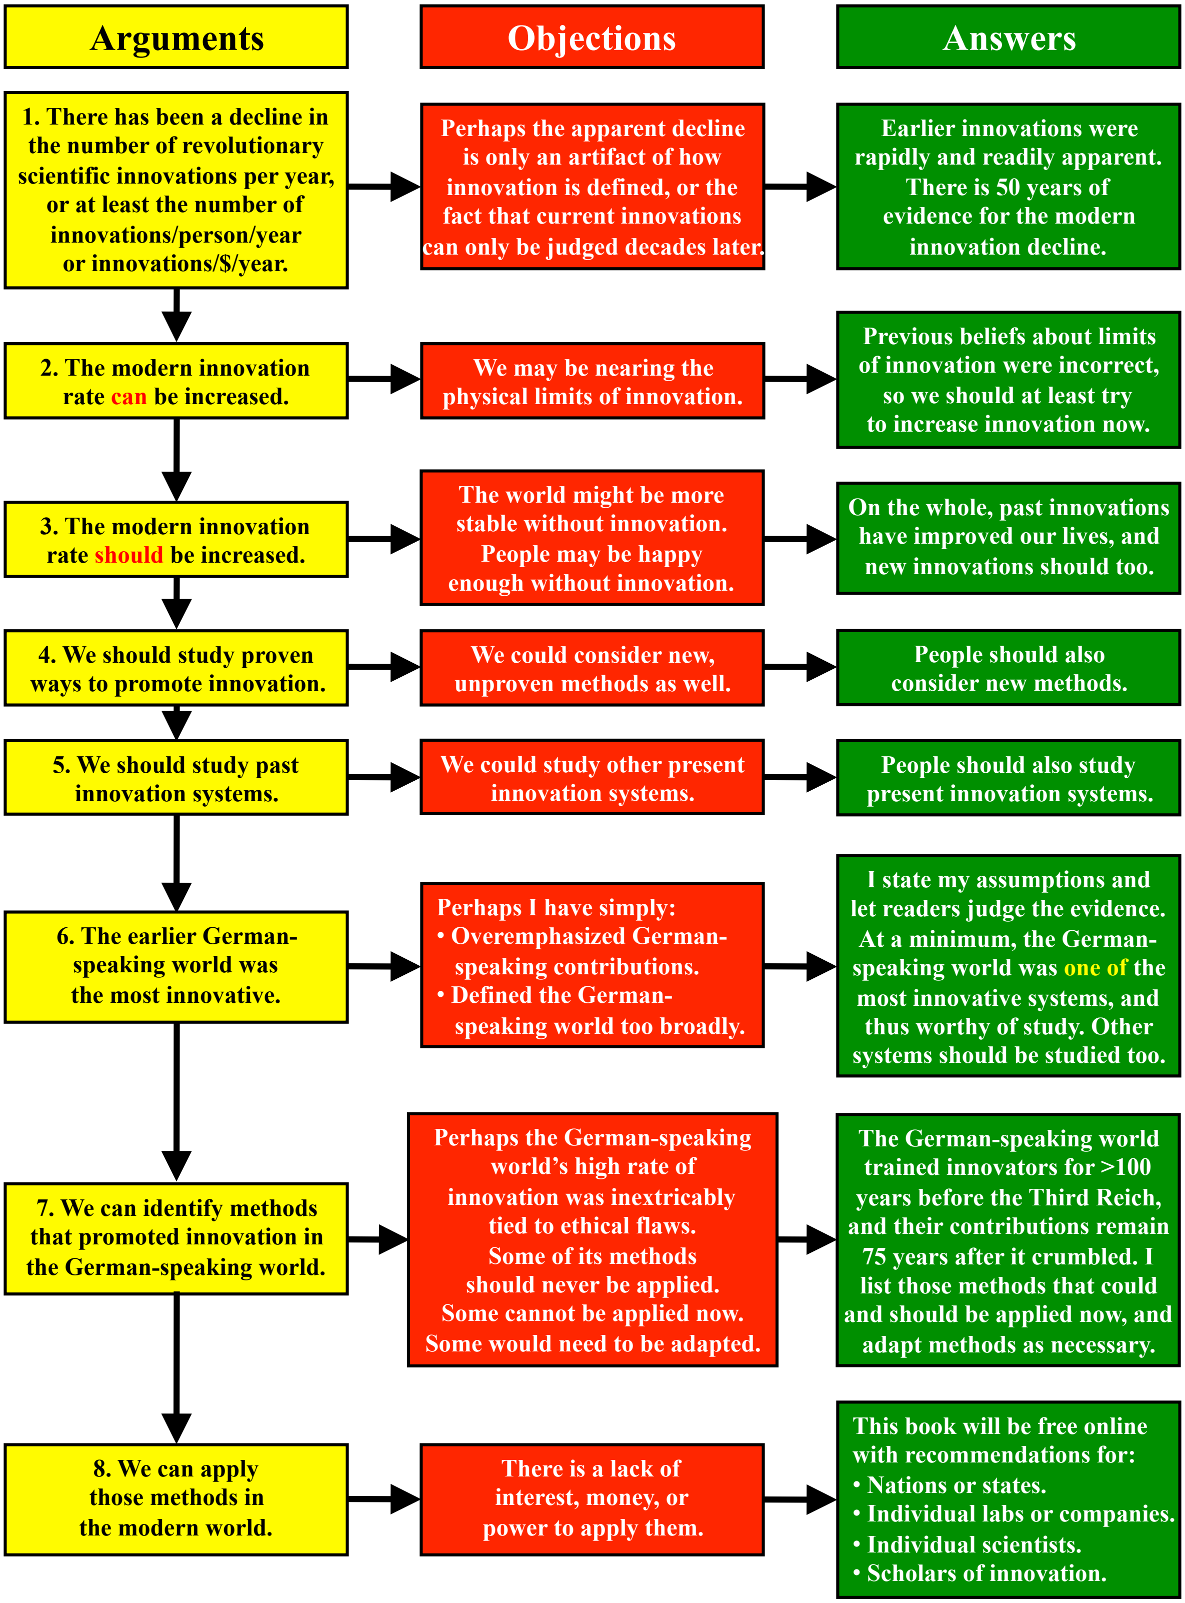
Before proceeding, it would be prudent to note several disclaimers, caveats, and assumptions, many of which are graphically illustrated in Fig. 1.7:

1. It should be emphasized that this study does not argue that the modern research system has produced no revolutionary innovations. Rather, this study proceeds based on the assumption (derived from the analyses of other scholars such as those cited in Section 1.1) that compared to earlier times, the modern system appears to have produced fewer revolutionary innovations per year, or at least fewer revolutionary innovations per year per person in the system, or fewer innovations per year per amount of money spent on the system.

    (a) One should certainly consider the possibility that the apparent decline in the innovation rate is only an artifact of how revolutionary innovation is defined. One should also bear in mind the possibility that it may appear that there has been a recent decline in innovation simply because there are large numbers of current innovations whose true impact can only be correctly viewed and judged in hindsight, many decades from now. Nonetheless, it seems unlikely that the recent innovation decline is merely an artifact of our perception. Whereas once the world changed dramatically every few years, due to discoveries that were made only a few years before their impact was felt, now the world appears to have been largely free of similarly revolutionary changes for half a century, with only a few exceptions.

    (b) Similarly, this study does not argue that non-revolutionary R&D is not important. Typically it takes far fewer people, far less time, and far less money to first come up with a revolutionary innovation than it does to then take that existing innovation and fully develop it all the way to a mature product. Therefore one would expect an optimally efficient research and development system to devote only a relatively small fraction of its people and funding to creating revolutionary new innovations, and most of its resources to perfecting previously created innovations. However, relative to previous periods that produced and perfected many revolutionary innovations, the modern system seems to be (i) devoting a smaller fraction of its resources to creating new innovations, and/or (ii) constructively advancing a smaller fraction of such innovations all the way through to later-stage development.

2. Having concluded that the modern innovation rate has declined, this study proceeds on the assumption that it is possible that the modern innovation rate **can** be increased. One cannot discount the possibility that we are simply nearing the physical limits of innovation. Perhaps most things that can be invented or discovered, within the constraints of human resources and interests, have already been invented or discovered. In that case, the innovation decline is due to the well of possibilities gradually running dry. On the other hand, on many previous occasions humanity has believed that it had reached the limits of innovation, and on each occasion it was mistaken (for example, during the Roman Empire; before each succeeding wave of the Industrial Revolution; once classical physics was mature but before quantum and relativistic physics were discovered; the state of medicine prior to the development of anesthetics, antiseptics, and antibiotics; etc.). Therefore, we should adopt the assumption that we are not now at an actual physical limit for innovation, and at least try to increase the innovation rate to see if any physical limits are encountered.



Arguments
Objections
Answers
1. There has been a decline in the number of revolutionary scientific innovations per year, or at least the number of innovations/person/year or innovations/$/year.
Perhaps the apparent decline is only an artifact of how innovation is defined, or the fact that current innovations can only be judged decades later.
Earlier innovations were rapidly and readily apparent. There is 50 years of evidence for the modern innovation decline.
2. The modern innovation rate can be increased.
We may be nearing the physical limits of innovation.
Previous beliefs about limits of innovation were incorrect, so we should at least try to increase innovation now.
3. The modern innovation rate should be increased.
The world might be more stable without innovation. People may be happy enough without innovation.
On the whole, past innovations have improved our lives, and new innovations should too.
4. We should study proven ways to promote innovation.
We could consider new, unproven methods as well.
People should also consider new methods.
5. We should study past innovation systems.
We could study other present innovation systems.
People should also study present innovation systems.
6. The earlier German-speaking world was the most innovative.
Perhaps I have simply: • Overemphasized German-speaking contributions. • Defined the German-speaking world too broadly.
I state my assumptions and let readers judge the evidence. At a minimum, the German-speaking world was one of the most innovative systems, and thus worthy of study. Other systems should be studied too.
7. We can identify methods that promoted innovation in the German-speaking world.
Perhaps the German-speaking world's high rate of innovation was inextricably tied to ethical flaws. Some of its methods should never be applied. Some cannot be applied now. Some would need to be adapted.
The German-speaking world trained innovators for >100 years before the Third Reich, and their contributions remain 75 years after it crumbled. I list those methods that could and should be applied now, and adapt methods as necessary.
8. We can apply those methods in the modern world.
There is a lack of interest, money, or power to apply them.
This book will be free online with recommendations for: • Nations or states. • Individual labs or companies. • Individual scientists. • Scholars of innovation.

Figure 1.7: Flowchart of the key arguments underlying this book, some possible objections, and answers to those objections.

3. Moreover, this study operates on the assumption that the modern innovation rate **should** be increased. Someone may object that the world might be more stable without innovation, or that people are currently happy enough without further innovation, and those objections do have some merit. Yet on the whole, past innovations have improved our lives. How many people would prefer to forsake modern technology and medicine and live as people did in the year 1900, or 1800, or 1200? Thus this study proceeds with the belief that at least on balance, new innovations will also improve people's lives and are morally and socially desirable.

4. Rather than trying to reinvent the wheel, this study focuses on studying already proven ways to promote innovation. It does not consider new, unproven methods to promote innovation, although other scholars certainly should propose and evaluate new methods as well.

5. Among those proven ways to promote innovation, this study specifically considers past innovation systems. With mountains of historical documentation and many decades of hindsight, it is more straightforward to fully evaluate past innovation systems and their ultimate impact than to properly evaluate present innovation systems around the world. Nevertheless, other scholars should be and are evaluating various current innovation systems worldwide, and there is much to learn from those studies.

6. Out of all past innovation systems, I wanted to focus on the most productive one, whatever that was. I eventually came to the conclusion that the German-speaking world was the most innovative, based on the number and the importance of the creators and creations summarized in Chapters 2–9 and the appendices, as well as considerable reading about other historical innovation systems. Readers are entirely welcome to disagree with my conclusion, but hopefully my presentation shows that the German-speaking world was at the very least **one of** the most innovative systems, and thus imminently worthy of detailed study.

    (a) Some readers may feel that I have overemphasized the contributions of the German-speaking world relative to those of other historical innovation systems. It is not at all my intent to belittle the scientific contributions of other places or times, which have been made by innovators ranging from Archimedes to Louis Pasteur to Rosalind Franklin. Ideally it would be desirable to analyze factors that have promoted innovation in all places and times, but in order to keep the scope manageable, I had to pick one innovation system, and I chose the German-speaking world of the nineteenth and early twentieth centuries. Nevertheless, I highly recommend that readers of this book seek out or even conduct their own studies of scientific innovations from other places and times. Such other studies may even find some of the same contributing factors as this study, or they may identify additional useful systemic methods for promoting innovation.

    (b) Other readers may object that I have inflated the accomplishments of the German-speaking world by defining that world too broadly. Admittedly, the topic I have chosen, revolutionary scientific innovations in the German-speaking world of the nineteenth and early twentieth centuries, has very fuzzy boundaries. One should certainly recognize that this topic could be defined in many other possible ways, with the boundaries of the topic set at other limits. I have chosen to define the boundaries very broadly in order to analyze as much data as possible. Another advantage of defining the boundaries so broadly in this study is that if some readers prefer to set different limits for the boundaries, it would be much easier for them to simply exclude some of the data I provide in order to shrink the boundaries than it would be for them to collect the large amounts of new data that would be required to expand the boundaries. The three major categories of boundaries used in defining the scope of this study are:

i. Spatial boundaries. Depending on personal preferences and definitions, the German-speaking world could be defined to include the Netherlands and parts of eastern Europe, as other scholars have done previously and I have done here, or those could be excluded. Even within that German-speaking world, there could be important differences in innovation systems in different regions, as that world was hardly homogeneous. Moreover, people, ideas, and methods flowed back and forth across national borders, and thus the German-speaking scientific world was never truly independent of the scientific communities in other regions. To deal with these difficulties, I have tried to define and analyze the system as a scientist would analyze a physical system: choosing a well-defined if somewhat arbitrary boundary around that system, studying what happens within that system, and keeping track of what flows into and out of that system across the boundary.

ii. Temporal boundaries. The German-speaking scientific world had a very long and very slow rise, with no clear beginning point. It was definitely booming by the time of German unification in 1871. In order to capture most of the rise, this book considers scientists and discoveries well before that date, back to around 1800, but other beginning dates could equally well be chosen. Likewise, the end date of the German-speaking world to be studied could easily be defined in different ways. When the Third Reich began in 1933, roughly 25% of scientists (mostly of Jewish background) left the German-speaking world, and conditions greatly changed for those who remained in it. By 1945, that world had been destroyed by a combination of the Third Reich's behavior, the Allied military campaign, and Allied removals of scientists and scientific material from the German-speaking world. The slow reconstitution of scientific systems in West and East Germany (and later in reunified Germany) and in Austria after 1945 is beyond the scope of this book, although the book does track the post-1945 worldwide contributions of scientists who had been educated primarily or entirely in the German-speaking world before 1945. Finally, of course, it must be recognized that national borders, governments, and population ethnic compositions changed repeatedly over the time period covered in this book.

iii. Intellectual boundaries. There are no clear-cut definitions for, and no obvious boundary between, truly revolutionary and more evolutionary (progress by incremental improvements) scientific work. I have tried to focus on the more revolutionary and innovative inventions and discoveries, as generally recognized in the sources listed in the Bibliography. The result cannot help but be somewhat arbitrary and definitely incomplete, yet I hope that it will serve as a representative selection to facilitate the overarching analysis in this book. In order to keep the scope manageable, I have excluded the social sciences—psychology, linguistics, philosophy, economics, and others—from this book; that is simply my personal choice, and there would undoubtedly be much to learn from other researchers who do address those areas. Also largely excluded are scientific failures and mediocrity in the areas covered by this book, simply because there is so little available literature and data on them compared to what exists for the much more visible successes. (I do not know how to readily rectify this deficiency, but I do at least want to acknowledge it.)

(c) This study is not intended to make an argument for nationalist or ethnic bragging rights. The scientific research world in question spanned several nations, and even several very different types of government within a single nation's history. The scientists had a wide variety of ancestral backgrounds. The key to their success appears to lie in their intellectual approach, not their nationality or ethnicity.

(d) This study does not mean to imply that there is anything unique or magical about the German language—speaking German does not make scientists smarter. "German-speaking" is used throughout this book as the most convenient phrase to describe a geographical region in central Europe, centered on the German-speaking countries of Germany, Austria, and Switzerland, but also spilling over to surrounding areas to which they were most closely coupled during the time period in question (especially the Netherlands and parts of Czechoslovakia, Poland, and Hungary). "German-speaking" is also employed throughout this book to describe scientists and engineers who received part or all of their training in that region, regardless of whether German was their primary language, or even the language in which most of their education and research were conducted. Thus "German-speaking" is used to denote a population of scientists who were molded by the research world in this central region of Europe, in order to facilitate the study of those scientists and of common factors in their training that may have contributed to their ultimate success.

(e) Similarly, the label "scientists" is used throughout this book as shorthand to denote people who contributed to scientific discoveries or technological inventions, even though those people included not only degreed scientists but also engineers, mathematicians, medical doctors, veterinarians, technicians, military personnel, and individuals with only incomplete or no formal scientific education who made important contributions.

(f) As a final note on definitions, "forgotten" is employed in this book's title to succinctly encapsulate the apparent overall trend regarding general worldwide awareness of these scientists. Of course I realize that some of these scientists (such as Albert Einstein, Edward Teller, and Wernher von Braun) became household names, that modern scientists will recognize many more names in some of these fields, and that huge numbers of books, articles, and encyclopedia entries have been written about various German-speaking scientists (as cited in the Bibliography). Nevertheless, I believe that most readers will find it as surprisingly enlightening as I have (i) to learn about many of the creators and creations that are included in this book, (ii) to realize that this limited portion of geography and time could produce revolutionary creators and creations with such overwhelming numbers and importance, and (iii) to consider what innovation-promoting approaches our modern world may be able to learn from that history. (One should also note that the problem of innovators not being properly recognized or remembered is not exclusive to German-speaking creators.)

(g) It is certainly not my intent to claim that all major innovations have come from German-speaking scientists, or even that all elements and steps in any given innovation have come from German-speaking scientists. Yet I believe the examples cited in this book show that the number of major innovative contributions by German-speaking scientists in the nineteenth and twentieth centuries was astoundingly large, and that those contributions have had a remarkably profound and long-lasting impact on our modern world. As already mentioned, even if the German-speaking world was only one of the top innovation systems and not the greatest one, then it warrants a detailed analysis to see what we can learn from it.

7. This study assumes that we can identify useful methods that promoted innovation in the earlier German-speaking world.
    (a) This study is at best a concise overview of a vast field encompassing the actions of thousands of scientists and engineers across many countries over a period of two centuries (including the post-1945 careers many of them had), as well as investigations of those innovators and their innovations by countless subsequent scholars. For much more information on people and projects that can only be briefly mentioned here, please consult the cited references and even their references. Due to space limits, this book cannot include all scientific fields or all creations and creators within each field. Nonetheless, hopefully the sizable numbers of fields, creations, and creators that have been included are sufficient to elucidate both the impact of the German-speaking creators and the systemic principles underlying their successes. Much more work on these topics could and should be conducted, however.

    (b) I do not mean to imply that the earlier German-speaking world was entirely different or unique; some of its innovation-promoting factors may also have been successfully implemented at other times and places, or may already be a part of the modern research system.

    (c) For those innovation-promoting factors that are different, one must recognize the larger differences that existed between the earlier German-speaking world and the modern world. A strategy that facilitated innovation in the older German-speaking world may need to be suitably adapted to operate successfully in the modern world. Other factors that promoted innovation in the earlier German-speaking world may not be possible or even desirable to implement now. Nonetheless, I hope that enough strategies can be identified and adapted to be beneficial.

    (d) Some people may only be familiar with research programs that were conducted during the Third Reich, or might wonder if perhaps the German-speaking world's high rate of innovation was inextricably tied to ethical flaws. In no way is this study an argument that the Third Reich had inherently superior scientific research approaches. This study focuses on innovators who were trained in the scientific world that existed for more than a century prior to the Third Reich, and many of them lived their entire productive careers before the Third Reich. For those creators whose productive careers extended beyond 1933, their careers and the scientific research world itself were greatly impacted or destroyed by the Third Reich.[8] The key is the earlier research world, which had a long and illustrious history prior to the Third Reich, and which produced creators and creations whose impact is still felt at least three-quarters of a century after the Third Reich crumbled.

---

[8] The Third Reich drove out, fired, imprisoned, and/or killed a large fraction of the creators. Most of the remaining creators were mistreated and misused, even if some of their creations did receive lavish funding. The Third Reich also caused huge numbers of its students (many of whom would have become future scientists) and some of its existing scientists to die fighting in the war, made the schools and universities highly ideological and dysfunctional, and made scientists focus their energies solely on developing military projects without also refilling the research pipeline by training the next generation of creators and making new discoveries in fundamental science. Even if the Third Reich had won the war, the German-speaking scientific world that had been so carefully cultivated by earlier generations would have been destroyed.

   (e) This study does not claim that research conditions in the earlier German-speaking world were ever perfect, even before the Third Reich came along. Throughout the time period and geographical areas in question, there were plenty of examples of interpersonal conflicts, discrimination, bureaucratic obstruction, overlooked innovators, insufficient job opportunities and funding, and other problems. Nonetheless, despite these pervasive and persistent human problems, the amount of revolutionary innovation per scientist in the earlier German-speaking world seems to compare quite favorably with that in the modern world.

   (f) Both to keep the scope and length manageable and also to concentrate on topics that have not been well addressed previously, this study is focused only on the factual questions of what innovations were created, what innovators created them, and what factors facilitated the development of those innovators and innovations. This study cannot even begin to address the large number of related ethical questions—whether certain innovations should have been created, how they should have been used, how innovators were treated by or behaved during the Third Reich, how Allied countries treated the German-speaking world after World Wars I and II, etc. There is a vast body of existing literature on such moral questions, and I highly recommend that all readers seek out those books and study them.[9]

8. The ultimate objective of this study is to make these methods of improving innovation available to the modern world. Yet I recognize that there may be a lack of interest, funding, or power to apply them. Accordingly, I have tried to do everything possible to ensure that this book will ultimately find a receptive audience at some time, place, and level.

   (a) I have divided the concluding recommendations into those that would require support from entire nations or states, those that could be implemented by individual organizations or laboratories, those that could be useful for individual scientists, and those that should be considered by scholars of innovation systems.

   (b) In order to maximize the potential audience, longevity, and impact of this study, I decided to make the document freely available on the internet instead of publishing it as a printed book, which might be expensive and difficult to obtain and might rapidly go out of print, as so many of the cited references have. An online resource also has the advantage that it can be periodically updated with corrections or additional information. In choosing this path, I am following the model of other researchers who have made large amounts of technical information freely available online, for example Carey Sublette's website (http://nuclearweaponarchive.org), Mark Wade's website (http://www.astronautix.com), and the website of the Stichting Centrum voor Duitse Verbindingen en aanverwante Technologieën (http://www.cdvandt.org).

---

[9] E.g., Bar-Zohar 1967; Beyerchen 1977; Black 2012a, 2012b, 2017; Borkin 1978; Bower 1987; Campbell and Harsch 2013; Cornwell 2003; Crim 2018; Deichmann 1996; Joseph Fisher 2017; Friedrich et al. 2017; Geissler 1998a, 1998b, 1999; Gellermann 1986; Georg 2012; Gimbel 1986, 1990a, 1990b, 1990c; Gröhler 1989; Guillemin 2005; Friedrich Hansen 1993; István Hargittai 2006; Harris Paxman 2002; Haunschmied et al. 2007; Hayes 2001; Heim et al. 2009; Hentschel and Hentschel 1996; Linda Hunt 1991; Jacobsen 2014; Jeffreys 2008; Karlsch and Laufer 2002; Kaszeta 2020; Kater 1989; Keynes 2019; Klee 2001; Kurowski 1982; Lasby 1971; Leff 2019; Le Maner and Sellier 2001; Julian Lewis 2002; Lichtblau 2014; Macrakis 1993; Milton Mayer 2017; Medawar and Pyke 2000; Mick 2000; Nachmansohn 1979; Nash 2013; Michael Neufeld 1995, 2002, 2003, 2007; Plumpe 1990; Posner and Ware 2000; Pringle 2006; Renneberg and Walker 1993; Sasuly 1947; Schambach 2011; Sellier 2003; Simpson 1988; Spitz 2005; Stoltzenberg 1994, 2005; Sutton 1976; Szöllösi-Janze 2001, 2015; Tucker 2006; Wachsmann 2015; Bernd Wagner 2000; Jens-Christian Wagner 2011, 2015; Wallace 2004; Whitman 2018.

   (c) For the same reasons, I decided to write this document in English, which currently is arguably the most widely accessible international language. I would be happy to offer advice or assistance with translating the contents into other languages if that would be of interest.

9. Here are a few final points:

   (a) **I have deliberately left a blank space where images of some creators or creations should go.** Those are people or projects that I felt were important enough that they should definitely be shown in this book, yet I have not yet been able to locate a suitable image that I have permission to use, despite my searches in Europe and in the United States. If readers have any relevant images and could send them to me, I would be very grateful and will include them in future editions of this book. Even where a suitable photo cannot be located, I believe that leaving a blank space pays tribute both to the scientific importance of that creator or creation and to how that historical fact has been very nearly forgotten.

   (b) Similarly, some first names, nationalities, or dates of birth and death are indicated as unknown if I have not been able to find them. Relevant information from readers would be very welcome.

   (c) Throughout the book, I have made a deliberate choice to quote experts and source documents on various topics as much as possible, rather than asking readers to accept my own account of innovators, innovations, events, and their importance. While the resulting text may not flow as smoothly as a unified narration, I hope that the presentation benefits far more from the objectivity and the persuasive amount of data that are afforded by this approach.

   (d) Lengthy or tangential sets of evidence have been placed in the appendices to avoid interrupting the flow of the discussion in the main chapters of the book.

      i. In order not to obscure the book's arguments by simply referring readers to numerous documents that may be difficult to obtain, relevant excerpts from a large number of key sources are presented in the appendices.

      ii. All or parts of some key documents are presented as photographs, which I have tried to make as clear and readable as possible, subject to the constraints of the original documents and the book format.

      iii. To make the contents computer-searchable for readers and internet search engines, most documents have been retyped (with annotations as appropriate).

      iv. Where I have retyped documents, I have tried to preserve the formatting of the original documents (underlining, etc.) as much as possible.

      v. To avoid variant spellings that would not come up in a computer text search, I have silently corrected some obvious typographical errors in some of the quoted source documents. U.S. and U.K. documents that were typed during and shortly after World War II were often careless in their spellings of the German names of people and places.

  vi. Neither archival documents nor cited reference works are guaranteed to be unbiased or free from error. In the text, and especially in Appendices A–E, I quote sources that I believe are worthy of serious consideration.[10] Some readers may come to different conclusions about the accuracy or interpretation of some of those sources. By making this collection of sources freely available, I hope to facilitate such discussions.

  vii. In order to avoid increasing the length of this already enormous book by a factor of several fold, I have abridged portions of the documents that seemed less relevant, as denoted by [...] in the quoted text.

  viii. Where I wanted to add emphasis to passages in quoted documents to draw the attention of readers, I have displayed those passages in red. Even passages not in red are relevant too, though, which is why I have taken the time to type them up and include them as well.

  ix. To add my own commentary regarding quoted documents yet clearly distinguish my commentary from the text of the source documents, [my commentary appears in blue text inside square brackets].

  x. Key sources not in English are presented in both their original language and a parallel English translation.

  xi. Citations direct interested readers to the original sources of these documents in case readers would like to verify their authenticity and read them in full.

  xii. Each source quote has been placed in the most relevant section, but it may be germane to other sections as well, as indicated by cross-references.

(e) The Bibliography is organized into a number of broad categories, instead of being one long list with everything mixed together. Hopefully any difficulties in figuring out in which category a citation may be found are greatly outweighed by the convenience to those who are interested in easily perusing all references on a given topic.

(f) Even though there is a tremendous amount of available literature in this field, many lifetimes could be spent pursuing answers to all of the important questions that remain. Those answers may lie in personal collections or official archives anywhere around the world, if new investigators are willing to take up the quest.

(g) Because the body of information on German-speaking innovators is both so large and so incomplete, this book cannot help but be incomplete and imperfect. **For readers who find that specific assumptions, definitions, information, arguments, or conclusions I have given are incorrect or incomplete, I would welcome any suggestions for improvements to future editions (ToddHRider@gmail.com or thor@riderinstitute.org).**

(h) At the very least, hopefully this book will spur discussion, learning, and further work in the important areas that it covers.

---

[10] In recent decades, the topic of advanced German wartime research has been plagued by some completely bogus documents and information. I have tried my best to exclude that here. Please let me know if you think I have included something that is bogus or excluded something that is real. Some references that are cited in the Bibliography but not quoted in the text are included simply for completeness, not as any endorsement of their quality.

Chapter 2

Creators and Creations in Biology and Medicine

O dieses ist das Tier, das es nicht giebt.
Sie wußtens nicht und habens jeden Falls
—sein Wandeln, seine Haltung, seinen Hals,
bis in des stillen Blickes Licht—geliebt.

Zwar *war* es nicht.
Doch weil sie's liebten, ward
ein reines Tier. Sie ließen immer Raum.
Und in dem Raume, klar und ausgespart,
erhob es leicht sein Haupt und brauchte kaum

zu sein. Sie nährten es mit keinem Korn,
nur immer mit der Möglichkeit, es sei.
Und die gab solche Stärke an das Tier,

daß es aus sich ein Stirnhorn trieb.
Ein Horn.
Zu einer Jungfrau kam es weiß herbei—
und war im Silber-Spiegel und in ihr.

Oh this is the animal that never was.
They didn't know that and dared nonetheless
to love its transformations, its bearing, its gait,
till in the tranquil gaze of light, it lived.

Really it never *was.*
Yet as they loved it, it
became a pure creature. They always left room.
And in that space, empty and set aside,
it lightly raised its head and scarcely needed

to be. They nourished it with no corn,
only and always with the possibility of being.
And that gave such strength to the creature,

that it grew a horn on its forehead.
One horn.
It came to a young woman, all white—
and was in the silver mirror and in her.

Rainer Maria Rilke. 1923.
Die Sonette an Orpheus [*Sonnets to Orpheus*]
Part II, 4. Leipzig: IM Insel.

This chapter gives an overview of some innovations in biology and medicine that have played major roles in the modern world and that were discovered or invented by scientists, doctors, and engineers who were trained in the predominantly German-speaking central European research world in the nineteenth and early twentieth centuries. As may be seen from the examples cited in this chapter, the large number, profound impact, and lasting nature of those contributions are quite striking.

Over the course of the nineteenth century, intellectual leadership in biology and medical research began to pass from primarily French and British scientists to largely German-speaking scientists.[1] France was weakened by nearly a century of continual political upheaval that followed the French Revolution. As extraordinarily farsighted and productive as Louis Pasteur and those gathered around him were, it is difficult to identify a widespread culture of comparable biologists in France by the late nineteenth century. Since previous centuries, at any given time the United Kingdom maintained a relatively small number of scientists who made enormously important biology and medical contributions; such British biologists still existed in the late nineteenth century (e.g., Charles Darwin, Alfred Russel Wallace, and Joseph Lister), yet their modest numbers became overwhelmed by the large numbers of talented German-speaking biologists. By the mid- to late-nineteenth century, German-speaking creators were also producing microscopes with the greatest clarity at high magnifications (Section 6.9), and that gave a further advantage to German-speaking biologists and doctors.

As covered in this chapter, creators from the German-speaking world made major contributions to:

2.1. Cellular and molecular biology

2.2. Microbiology and immunology

2.3. Neuroscience

2.4. Cardiovascular medicine

2.5. Vitamins and hormones

2.6. Developmental biology and embryology

2.7. Aerospace medicine and other aspects of physiology

2.8. Botany

---

[1] In addition to specific references that are cited in different areas throughout this chapter, this chapter makes use of general biographical and project information from: ACLS 2000; Albrecht et al. 1992; Ash and Söllner 1996; Bar-Zohar 1967; Bower 1987; Bunch and Hellemans 2004; Challoner 2009; Cornwell 2003; Crim 2018; EB 1911, 2010; Gillispie 1970–1990; Gimbel 1990a; Glatt 1994; Hall 2019a; István Hargittai 2006, 2011; Linda Hunt 1991; Impey et al. 2008; Jacobsen 2014; Koertge 2007; Kurowski 1982; Lasby 1971; Lusar 1956, 1971; Medawar and Pyke 2000; Mick 2000; Murray 2003; Nachmansohn 1979; NDB 1953–2020; Neufeld 2012; Nouzille and Huwart 1999; O'Reagan 2014, 2019; Porter 1994; Charles Walker 1946; Peter Watson 2010; Weitensfelder 2009.

For general overviews of large portions of the history of biology and medicine in the German-speaking world, see: Deichmann 1996; Gedeon 2006; Henry Harris 1999; Jahn 2004; Junker 2004; Kohler 2008; Lagerkvist 1998, 2003, 2005; Magner 2002; Morange 2020; von Schwerin 2013; Simmons 2002.

I have deliberately left a blank space where images of some creators or creations should go. Those are people or projects that I felt were important enough that they should definitely be shown in this book, yet I have not yet been able to locate a suitable image that I have permission to use, despite my searches in Europe and in the United States. If readers have any relevant images and could send them to me, I would be very grateful and will include them in future editions of this book. Even where a suitable photo cannot be located, I believe that leaving a blank space pays tribute both to the scientific importance of that creator or creation and to how that historical fact has been very nearly forgotten.

German-speaking creators also made numerous contributions to other biomedicine-related areas listed in Chapters 3 (chemistry), 6 (optical and electron microscopy), and 8 (nuclear medicine).

A widely held view among historians of science is that German-speaking scientists lagged significantly behind other parts of the world in the field of biotechnology [Szöllösi-Janze 2001, pp. 112–114]. As shown in this chapter and in Appendix A, German-speaking scientists actually led the world in developing most of the knowledge, tools, methods, and applications of biotechnology: culture of prokaryotic (bacteria) and eukaryotic (yeast, animal, and plant) cells for laboratory and industrial applications, DNA extraction and study, immunoassays, enzymes, etc.

Even American and British officials overseeing the transfer of science and technology from Germany to the United States after World War II were shocked by the quantity and quality of biology-related innovations, and they recorded some of them for history. For example, in September 1945, R. P. Linstead and T. J. Betts, the British and American chairs of the Combined Intelligence Objectives Subcommittee (CIOS), listed a number of important German innovations regarding pharmaceuticals [AFHRA A5186 electronic version pp. 904–1026, Ch. 4, p. 57]:

> In the field of new pharmaceuticals a wide range of new products were discovered by CIOS investigators. In the majority of instances, German testing methods were inadequate to provide conclusive proof of their efficacy. The following pharmaceuticals were of special interest.
>
> 1. A method of producing inactive insulin by emincing fresh glands in alcohol. This process results in much higher yields than those obtained by conventional methods.
> 2. Improved analgesics and hypnotics.
> 3. The use of DDD (German designation, ME-1700) as an insecticide. Germans claims that this product is more effective than DDT are currently being investigated. If these claims are substantiated, the product would prove of great value since it can be produced more cheaply than DDT, and is less toxic to warm blooded animals.
> 4. The development of peristone or synthetic blood plasma.
> 5. A new sulpha compound which had been synthesized, but not tested clinically.
>
> The Germans were discovered to be using automatic machinery for filling and sealing ampules. The advantages of this machinery are many: it eliminates the imperfect sterilization, low output, inaccurate dosage, loss through spilling and high operating cost which is characteristic of hand methods.

In a lengthy magazine article published in the United States in 1946, journalist Charles Lester Walker gave a much longer list of examples he had learned from U.S. government personnel overseeing the technology transfer [Charles Walker 1946]:

> In matters of food, medicine, and branches of the military art the finds of the search teams were no less impressive. And in aeronautics and guided missiles they proved to be downright alarming. One of the food secrets the Nazis had discovered was a way to

sterilize fruit juices without heat. The juice was filtered, then cooled, then carbonated and stored under eight atmospheres of carbon-dioxide pressure. Later the carbon-dioxide was removed, the juice passed through another filter—which, this time, germ-proofed it—and then was bottled. Some thing, perhaps, for American canners to think about.

Milk pasteurization by ultra-violet light has always failed in other countries, but the Germans had found how to do it by using light tubes of great length, and simultaneously how to enrich the milk with vitamin D.

At a plant in Kiel, British searchers of the Joint Intelligence Objectives Committee found that cheese was being made—"good quality Hollander and Tilitser"—by a new method at unheard-of speed. "Eighty minutes from the renneting to the hooping of the curd," report the investigators. The cheese industry around the world had never been able to equal that.

Butter (in a creamery near Hamburg) was being produced by something long wished for by American butter makers: a continuous butter making machine. An invention of dairy equipment manufacturers in Stuttgart, it took up less space than American churns and turned out fifteen hundred pounds an hour. The machine was promptly shipped to this country to be tested by the American Butter Institute.

Among other food innovations was a German way of making yeast in almost limitless quantities. The waste sulfite liquor from the beechwood used to manufacture cellulose was treated with an organism known to bacteriologists as candida arborea at temperatures higher than ever used in yeast manufacture before. The finished product served as both animal and human food. Its caloric value is four times that of lean meat, and it contains twice as much protein.

The Germans also had developed new methods of preserving food by plastics and new, advanced refrigeration techniques. Refrigeration and air-conditioning on German U-boats had become so efficient that the submarines could travel from Germany to the Pacific, operate there for two months, and then return to Germany without having to take on fresh water for the crew. A secret plastics mixture (among its ingredients were polyvinyl acetate, chalk, and talc) was used to coat bread and cheese. A loaf fresh from the oven was dipped, dried, redipped, then heated half an hour at 285 degrees. It would be unspoiled and good to eat eight months later.

"As for medical secrets in this collection," one Army-surgeon has remarked, "some of them will save American medicine years of research; some of them are revolutionary[...]"

German medical researchers had discovered a way to produce synthetic blood plasma. Called capain, it was made on a commercial scale and equalled natural plasma, in results. Another discovery was periston, a substitute for the blood liquid. An oxidation production of adrenalin (adrenichrome) was produced in quantity successfully only by the Nazis and was used with good results in combating high blood pressure (of which 750,000 persons die annually in the United States). Today we have the secret of manufacture and considerable supply.

2.1 Cellular and Molecular Biology

Scientists from the greater German-speaking world were responsible for many of the major discoveries and innovations in cellular and molecular biology.[2] For convenience, in this section the creators and creations in cellular and molecular biology are divided into five (somewhat arbitrary and overlapping) categories:

2.1.1. Cell biology

2.1.2. DNA and genetics

2.1.3. Cancer

2.1.4. Proteins and enzymes

2.1.5. Mitochondria, respiration, and metabolism

The impressive history of cell biology in the German-speaking world is very well documented. One could also make a strong case that scientists from the German-speaking world essentially founded the whole field of molecular biology, dealing with the structures, natural functions, and artificial manipulation of important biological molecules such as DNA (deoxyribonucleic acid), RNA (ribonucleic acid), and proteins. This section provides a brief summary; see Appendix A for some relevant archival documents.

2.1.1 Cell Biology

As shown in Figs. 2.1–2.6, the majority of important pioneers of cell biology were from the predominantly German-speaking scientific world. One should certainly not overlook the importance of some British microscopists such as Robert Hooke (English, 1635–1703) and Robert Brown (Scottish, 1773–1858), as well as some French microscopists such as Henri Dutrochet (1776–1847) and François-Vincent Raspail (1794–1878) [Henry Harris 1999]. Nonetheless, over the course of the nineteenth century, those relatively small numbers of British and French microscopists were overwhelmed by the rapidly rising numbers and discoveries of German-speaking biologists, as well as the improved tools for microscopy that were also coming out of the German-speaking world (Section 6.9).

Although this book focuses primarily on scientific history from around 1800 onward, it would be impossible not to mention Antonie van Leeuwenhoek (Dutch, 1632–1723), who created the first known microscope and used it to observe numerous types of single-celled and multicellular organisms [Dobell 1960]. See pp. 1260 and 1267 for more information.

---

[2] For good overviews of portions of the history of cellular and molecular biology in the German-speaking world, see especially: Deichmann 1996; Dominguez-Lacasa 2005; Gausemeier 2005; Gedeon 2006; Henry Harris 1999; Holmes 1993; Höxtermann and Sucker 1989; Jahn 2004; Junker 2004; Kohler 2008; Krebs 1981; 2005; Magner 2002; Perutz 1989, 1998; von Schwerin 2013; Simmons 2002 Stoff 2012.

Johann Purkinje (Austrian/Czech, 1787–1869, Fig. 2.1) was arguably the founder of histology, the microscopic study of cells from different tissues in the body. He used the improved microscopes that were becoming available during the nineteenth century to study features of cells, especially those from the central and peripheral nervous systems. Purkinje (and independently, Wilhelm His Sr., p. 377) invented the first practical microtome for making extremely thin slices from animal organs or plants, and used that method to more easily visualize tissue structures under the microscope. He also developed the use of balsam tree sap to seal microscope slides and preserve them indefinitely. The *Encyclopedia Britannica* explained some of his scientific innovations and discoveries [EB 2010]:

> [P]ioneer Czech experimental physiologist whose investigations in the fields of histology, embryology, and pharmacology helped create a modern understanding of the eye and vision, brain and heart function, mammalian reproduction, and the composition of cells.
>
> Considered the founder of laboratory training in connection with university teaching in Germany, Purkinje is best known for his discovery of large nerve cells with many branching extensions found in the cortex of the cerebellum of the brain (Purkinje cells; 1837) and of the fibrous tissue that conducts the pacemaker stimulus along the inside walls of the ventricles to all parts of the heart (Purkinje fibres; 1839). In describing young animal embryos, he introduced protoplasm as a scientific term.
>
> First to use the microtome (a mechanical device for slicing thin tissue sections), glacial acetic acid, potassium bichromate, and Canada balsam in the preparation of tissue samples for microscopic examination. Purkinje also described the experimental effects on humans of camphor, opium, belladonna, and turpentine (1829) and the visual images produced by poisoning with digitalis and belladonna. He discovered the sweat glands of the skin (1833) and the germinal vesicle, or nucleus of the unripe ovum, that now bears his name (1825), recognized fingerprints as a means of identification (1823), and noted the protein-digesting power of pancreatic extracts (1836).

Building on the work of Purkinje, Johannes Peter Müller (German states, 1801–1858, Fig. 2.1) expanded the field of histology, studying both the macroscopic and the microscopic features of tissues from a wide variety of animal and human samples. In addition to his own research, he had an enormous scientific impact through the students whom he trained; he was the doctoral advisor for future luminaries such as Hermann von Helmholtz, Jakob Henle, Robert Remak, Theodor Schwann, and Rudolf Virchow.

Franz Meyen (Prussian, 1804–1840, Fig. 2.1), a botanist and microscopist, published a series of plant physiology books in the 1830s in which he wrote that plants were divided into many similar cells, and that new cells arose from the division of existing cells. Both of those discoveries were foundational to the field of cell biology.

Matthias Schleiden (German 1804–1881, Fig. 2.2) studied a variety of plants and plant tissues under the microscope and was another of the first scientists to recognize that larger organisms are divided into many similar cells. He studied the cell nucleus, cell division, and other aspects of cells. Oxford University's *Biographical Dictionary of Scientists* listed some of his discoveries [Porter 1994, pp. 607–608]:

> German botanist who, with Theodor Schwann, is best known for the establishment of the cell theory. [...]

> Schleiden was the first to recognize their importance as the fundamental units of living organisms when, in 1838, he announced that the various parts of plants consist of cells or derivatives of cells. [...]
>
> Schleiden also researched into other aspects of cells. He recognized the importance of the nucleus (which he called the cytoblast) in cell division[...] In addition, he noted the active movement of intracellular material in plant tissues[...]

Rudolph Wagner (German states, 1805–1864, Fig. 2.2) conducted microscopic research on the central and peripheral nervous systems, egg cells, and other tissues.

Jakob Henle (German, 1809–1885, Fig. 2.2) studied with Johannes Müller before having his own successful career studying and cataloging the macroscopic and microscopic features of tissues from a wide variety of organs.

Theodor Schwann (German, 1810–1882, Fig. 2.2) showed that animal tissues were composed of cells with nuclei and other features, just as Meyen and Schleiden had shown for plants. He studied a wide range of tissues under the microscope and classified cells by their features and apparent functions. Oxford University's *Biographical Dictionary of Scientists* described some of his research [Porter 1994, p. 611]:

> In 1834, Schwann began to investigate digestive processes and two years later isolated from the lining of the stomach a chemical responsible for protein digestion, which he called pepsin. This was the first enzyme to be isolated from animal tissue[...] Schwann then studied fermentation and between 1836 and 1837 showed that the fermentation of sugar is a result of the life processes of living yeast cells (he later coined the term metabolism to denote the chemical changes that occur in living tissue). [...]
>
> Giving numerous examples from many different types of animal tissues, Schwann in his *Microscopical Researches* concluded that all organisms (both animals and plants) consist entirely of cells or of products of cells and that the life of each individual cell is subordinated to that of the whole organism. The cell theory soon became widely accepted and is today recognized as being one of the most important concepts in biology.
>
> Schwann also discovered the cells (now called Schwann cells) that make up the myelin sheath surrounding peripheral nerve axons, and the striated muscle in the upper region of the oesophagus. In addition, he noted that an egg is a single cell that eventually develops into a complex organism—a basic principle in embryology.

Gabriel Gustav Valentin (German, 1810–1883, Fig. 2.3) worked with Purkinje and then moved to Switzerland, where he continued to study the histology of many different organs.

Rudolf von Kölliker (Swiss, 1817–1905, Fig. 2.3) catalogued important characteristics and structures of cells from skeletal or striated muscle, smooth muscle, skin, both, blood vessels, the central and peripheral nervous systems, and other tissues. He also investigated tissues in a wide variety of animals and embryos. The American Council of Learned Societies summarized some of his contributions [ACLS 2000, p. 495]:

> [...A]warded Ph.D. at Zurich for determining cellular nature of spermatozoa of invertebrates (1841); awarded M.D. from Heidelberg (1842). [...R]ecognized cellular nature of

> muscle fibers (1846)[...] Published *Mikroskopische Anatomie* (1850–54), which presented study of tissue in terms of cell theory; Koelliker's classification of tissues, presented in *Handbuch der Gewebelehre des Menschen* (1852), became accepted throughout Europe. Also employed cell theory in interpreting development of the embryo; demonstrated that same types of developmental processes occur in both invertebrates and vertebrates; viewed the egg as single cell. Suggested that the nucleus transmitted inherited characteristics (1841) and foreshadowed De Vries's theory of mutations; helped substantiate doctrine of the neuron as basic unit of nervous system (*circa* 1884) [...] he helped establish histology and cytology as independent branches of science.

Joseph von Gerlach (German, 1820–1896, Fig. 2.3) was one of the main developers of modern microscope stains, which stain different substances different colors and make it much easier to see cellular features that would otherwise be essentially transparent structures within a transparent fluid. He was also one of the originators of photomicrography, so that microscopic structures could be shown by actual photographs instead of hand-drawn sketches.

Rudolf Virchow (German, 1821–1902, Fig. 2.4) greatly elaborated on the earlier work by Schwann and others, publishing voluminous writings on the microscopic features of various cells and tissues, as well as their roles in the origins of numerous diseases such as cancer and arthritis. He also made fundamental contributions in many other fields. The *Encyclopedia Britannica* gave some idea of the diversity of Virchow's interests and achievements [EB 2010]:

> German pathologist and statesman, one of the most prominent physicians of the 19th century. He pioneered the modern concept of pathological processes by his application of the cell theory to explain the effects of disease in the organs and tissues of the body. He emphasized that diseases arose, not in organs or tissues in general, but primarily in their individual cells. Moreover, he campaigned vigorously for social reforms and contributed to the development of anthropology as a modern science. [...]
>
> As an intern at the Charité Hospital, he studied pathological histology and in 1845 published a paper in which he described one of the two earliest reported cases of leukemia. This paper became a classic. [...]
>
> Early in 1848 Virchow was appointed by the Prussian government to investigate an outbreak of typhus fever in Upper Silesia; his subsequent report laid the blame for the outbreak on social conditions and on the government.
>
> In 1859 he was elected to the Berlin City Council, on which, for the rest of his life, he focused on public health matters, such as sewage disposal, the design of hospitals, meat inspection, and school hygiene. He supervised the design of two large new Berlin hospitals, the Friedrichshain and the Moabit, opened a nursing school in the Friedrichshain Hospital, and designed the new Berlin sewer system.
>
> His work on the role of animal parasites, especially trichina, in causing disease in humans was fundamental and led to his own public interest in meat inspection. In 1874 he introduced a standardized technique for performing autopsies, by the use of which the whole body was examined in detail, often revealing unsuspected lesions.
>
> In 1865 Virchow discovered pile dwellings in northern Germany, and in 1870 he started

> to excavate hill forts. [...H]e accompanied Schliemann to Troy in 1879 and to Egypt in 1888.

Max Schultze (German, 1825–1874, Fig. 2.5) studied cellular structures and developed methods of classifying different types of cells.

Karl Wilhelm von Kupffer (Baltic German, 1829–1902, Fig. 2.5) conducted wide-ranging work in histology, studying cells from the central nervous system, kidneys, pancreas, spleen, blood vessels, and other tissues, as well as from embryos.

By studying plant cells under the microscope, Wilhelm Pfeffer (German, 1845–1920, Fig. 2.5) discovered the importance of osmotic pressure, and he developed methods to measure it.

Paul Mayer (German, 1848–1923, Fig. 2.5) further improved and systematized the microscope staining methods that had been introduced by Joseph von Gerlach and others.

A number of German-speaking scientists helped to develop methods of isolating cells from larger organisms and using "tissue culture" techniques to keep those cells alive and even get them to reproduce under laboratory conditions (Fig. 2.6).[3]

Wilhelm Roux (German, 1850–1924) conducted the first animal cell tissue culture experiments in 1885, removing medullary plate cells from a chicken embryo and keeping them alive in culture for 13 days.

Paul Grawitz (German, 1850–1932) experimented with tissue culture of additional animal cell types in the 1890s.

Gottlieb Haberlandt (Austrian, 1854–1945) developed plant cell tissue culture and also discovered totipotency, the ability of some "stem" cells to give rise to any type of specialized cell in an organism, in 1902. He was the father of Ludwig Haberlandt, who invented oral contraceptives (p. 354).

Paul Alfred Weiss (Austrian, 1898–1989) moved to the United States in 1930 and helped to develop improved methods for animal tissue culture there.

At the Friedrich Loeffler Institute, Friedrich Hecke (German?, 18??–19??), successfully demonstrated the first practical cultivation of viruses in tissue culture: foot-and-mouth disease virus (1930) and hog cholera virus (1932). Growing viruses in tissue culture is an immensely powerful technique that is now widely utilized to conduct preliminary tests of the properties of viruses and potential treatments for viruses much more rapidly and cheaply than can be done in animals. Tissue culture of viruses also became an important and widespread method of preparing "safe" versions of viruses to make vaccines that will protect humans or animals against the real version of the virus.

Other German-speaking scientists who contributed to cell biology are listed in other sections in this chapter, if their work was especially applicable to DNA, neuroscience, embryology, botany, or other areas.

---

[3] Ross Harrison (American, 1870–1959) began testing animal cell tissue culture methods in the United States in 1907, and is much better known in the English-speaking world than the earlier German-speaking tissue culture pioneers. It would be quite helpful for someone to write a deeply researched history of the early development of animal and plant tissue culture in the German-speaking world, including the work by and influence of Wilhelm Roux, Paul Grawitz, Gottlieb Haberlandt, Paul Alfred Weiss, Friedrich Hecke, and others.

2.1.2 DNA and Genetics

As shown in Fig. 2.7, DNA (deoxyribonucleic acid) is divided into several chromosomes in the nucleus of a cell. DNA forms a double-stranded helix, in which each strand is composed of a sequence of four possible bases or nucleotides: adenine (A), cytosine (C), guanine (G), and thymine (T). Each A on one strand is electrostatically attracted to a T on the other strand, and each C is attracted to a G. The bases of a strand are connected via a chain of alternating sugar and phosphate groups. RNA (ribonucleic acid) is very similar but uses a uracil (U) base instead of T.

German-speaking scientists founded and dominated the field of DNA and genetics research until World War II (with the exception of a few early foreign scientific competitors, chiefly the American Thomas Hunt Morgan and his students).[4] See Figs. 2.8–2.24. The dissemination of their discoveries (and in many cases, the diaspora of the scientists themselves) before, during, and after the war seeded research in this field around the world.

Franz Andreas Bauer (Austrian, 1758–1840) studied plants under the microscope and painted what he saw. He was the first or one of the first scientists to observe and depict the nuclei of cells (before the Scottish scientist Robert Brown, who is usually given credit in English-language science history books).

Franz Unger (Austrian, 1800–1870) worked in the fields of paleontology, plant physiology, and microscopy. He proposed that elements inside plant cells carry hereditary traits, and those ideas later influenced Gregor Mendel. He also suggested that the descendants of species could gradually evolve into other species over generations—before Charles Darwin, who garnered much more attention.

Hugo von Mohl (German, 1805–1872) studied plant cells under the microscope too. He was responsible for naming the contents of the cell the "protoplasm." He was also the first or one of the first scientists to observe mitosis, or the division of one cell and its nucleus into two cells, each with its own nucleus.

Robert Remak (Prussian, 1815–1865) observed and confirmed the process of mitosis for cell division, and in addition was one of the founders of the field of developmental biology and embryology.

Carl Wilhelm von Nägeli (Swiss, 1817–1891) studied the division of nuclei in cellular mitosis, as well as the fusion of nuclei in plant pollination.

Harald Bagge (German, 1817–1895) noted that in mitosis, the division of the nucleus occurs before the division of the cell.

Franz Leydig (German, 1821–1908) also studied the process of mitosis for various cell types.

As is now well known, Gregor Mendel (Austrian, 1822–1884) discovered the rules of genetics using plants he grew at his monastery, and meticulously documented his discoveries and explanations in a lengthy book. See Fig. 2.8. It is less well known that Mendel also conducted research in several other fields, including astronomy and meteorology. Oxford University's *Biographical Dictionary of*

Scientists summarized Mendel's research on genetics [Porter 1994, p. 475]:

> Mendel began the experiments that led to his discovery of the basic laws of heredity in 1856. Much of his work was performed on the edible pea (*Pisum* sp.), which he grew in the monastery garden. He carefully self-pollinated and wrapped (to prevent accidental pollination by insects) each individual plant, collected the seeds produced by the plants, and studied the offspring of these seeds. [...] Mendel also studied other characteristics in pea plants, such as flower colour, seed shape and flower position, finding that, as with height, simple laws governed the inheritance of these traits. From his findings Mendel concluded that each parent plant contributes a factor that determines a particular trait and that the pairs of factors in the offspring do not give rise to an amalgamation of traits. These conclusions, in turn, led him to formulate his famous law of segregation and law of independent assortment of characters, which are now recognized as two of the fundamental laws of heredity.
>
> Mendel reported his findings to the Brünn Society for the Study of Natural Science in 1865 and in the following year he published *Experiments with Plant Hybrids*, a paper that summarized his results.

Wilhelm Hofmeister (German, 1824–1877) was the first or one of the first scientists to identify and study individual chromosomes within the nuclei of plant cells.

August Weismann (German, 1834–1914) proposed methods by which cellular material could be inherited from one generation to the next and could lead to the evolution of species. He studied cell division and was the first to distinguish between mitosis (cell division that leads to two identical cells with the same numbers of chromosomes as the original cell) and meiosis (cell division that creates sperm and egg cells with half the numbers of chromosomes as the original cell).

Wilhelm von Waldeyer-Hartz (German, 1836–1921) studied and gave the name "chromosomes" to the individual components of the nucleus.

Johannes Friedrich Miescher (Swiss, 1844–1895) purified DNA (which he called nuclein) from cellular nuclei and suggested that the DNA could be involved in heredity. See Fig. 2.9. Historian of science Lois Magner explained Miescher's research [Magner 2002, pp. 422–423]:

> After receiving his M.D. degree (1868), Miescher began his remarkable studies of the physiological chemistry of pus cells [white blood cells], which were obtained by washing out used bandages from the surgical clinic. Given the high rate of postsurgical infection found in European hospitals at the time, a plethora of pus cells was always available. Attempting to purify pus cell nuclei, Miescher subjected his preparations to an acid extract of pig gastric mucosa (a crude preparation of the protein-digesting enzyme called pepsin). After this treatment, Miescher obtained an organic acid that had a remarkably high phosphorus content. The solubility properties of this substance, and its resistance to pepsin, suggested that it was a previously unknown cell constituent. Although this novel material was not well characterized, it was given the name *nuclein*. Later Miescher demonstrated that nuclein could also be isolated from salmon sperm. [...]
>
> [H]e did suggest that if some substance in the sperm were the specific cause of fertilization, it would have to be nuclein. [...] Privately, Miescher speculated on the possible role of nuclein in the transmission of heritable traits.

Walther Flemming (German, 1843–1905) was the one who dubbed the usual process of cell division "mitosis." Beginning in 1873, he conducted extensive studies of the structure and behavior of chromosomes in various cell types and in cell division, as shown in Fig. 2.10.

Eduard Strasburger (Polish/German, 1844–1912) studied the chromosome distribution in mitotic and meiotic cell division, and coined the words "nucleoplasm" and "cytoplasm" for the contents of the nucleus and the rest of the cell.

Hugo de Vries (Dutch, 1848–1935) rediscovered the rules of genetics after Mendel, and attributed the inherited traits to microscopic particles he called "pangenes," which was later shorted to "genes." He dubbed changes in genes "mutations," and explained the importance of mutations for evolution. He was also the first scientist to propose that homologous recombination or crossing over occurs between two chromosomes of the same type during meiosis.

Oskar Hertwig (German, 1849–1922) studied and reported details of the processes of mitosis and meiosis, and stated that DNA (nuclein) was the material that carried hereditary traits. He was the father of Paula Hertwig, who also conducted DNA research.

Wilhelm Roux (1850–1924) studied the role of chromosomes in fertilization and cell division. He was also one of the founders of the field of developmental biology.

Richard Altmann (German, 1852–1900) built on Miescher's work to purify DNA (nuclei), confirming that the substance was acidic and naming it "nucleic acid" in 1889.

Carl Rabl (Austrian, 1853–1917) tracked individual chromosomes through the stages of replication and cell division.

Albrecht Kossel (German, 1853–1927), shown in Fig. 2.11, determined the chemical composition of nucleic acids purified from cells. He showed that nucleic acids contain five different bases: adenine, cytosine, guanine, thymine, and uracil (including both DNA and RNA). Kossel found that those bases were connected via linkages of sugars and phosphates. He also isolated and studied proteins that bind to nucleic acids in the nucleus, which were determined to be histones and other accessory proteins [Mary Ellen Jones 1953]. For these discoveries, he won the Nobel Prize in Physiology or Medicine in 1910. Professor the Count K. A. H. Mörner, Rector of the Royal Caroline Institute, explained the revolutionary importance of Kossel's research on both nucleic acids and proteins [https://www.nobelprize.org/prizes/medicine/1910/ceremony-speech/]:

> The cells of the organism exhibit on the one hand certain special characteristics according to the organs to which they belong and on the other hand general, shared characteristics as well. It has long been known, and is easy to demonstrate, that the main mass of their organic substance consists of materials belonging to the group of protein bodies. They are however dissimilar in different cases. The development of protein chemistry in general, and of the specialized knowledge of the protein bodies occurring in cells and of the combined forms in which they appear, is therefore an important link in the chain of knowledge of cell chemistry and consequently also a factor of great importance in research on cellular life and functions.
>
> [...] Professor Kossel has since then enlarged the knowledge by the discovery of new, related substances, and in particular he has, by means of extensive work using new methods which he himself elaborated, carried the knowledge of the quantitative rela-

> tionships of these substances in the protein molecule further than is the case for the other protein breakdown products.
>
> There are several kinds of proteins. One group which is included here are the so-called protamines obtained from the milt of fish. Kossel has made a detailed study of these. For these a relatively simple structure has been discovered inasmuch as the number of dissimilar atom groups in them is not very great. They therefore present simpler relationships than proteins in general, and consist mainly of substances belonging to the group which I have just called basic breakdown products of protein. For certain protamines Kossel, thanks to his methods of determination, has in fact been able to establish the quantitative relationships of the building blocks making up these protamines, a goal which we seem to be far from attaining where the other proteins are concerned. [...]
>
> One protein group, first observed by Kossel, consists of the so-called histones. They stand between the protamines and what is termed ordinary protein. This group, again, is important because of its occurrence as a component of certain cells, and has also been studied in detail by Kossel.
>
> Professor Kossel has made an extensive and important study of the problem of the protein compounds in cells. As we have already mentioned, the proteins are very complex bodies. Within the cells the relationships are further complicated by the fact that the proteins there are combined in varying degrees with other substances such as those grouped under the name of "nucleic acids". These, too, are far from simple in structure. They form phosphorus-containing organic substances which, together with a form of phosphoric acid, usually contain purine bodies, pyrimidine bodies and a form of sugar or related substance. Professor Kossel has devoted a great part of his activity to these problems. It is not practicable to give an account of the details without taking up too much time, and they must therefore be passed over on this occasion. I will restrict myself to remarking that these nucleic acids by their presence in the cells and their relation to the protein bodies found there, certainly possess a great biological significance; and furthermore I should like to emphasize that it is to Kossel and his pupils especially that we owe our present advanced knowledge of these problems.

Wilhelm Weinberg (German, 1862–1937) rediscovered and extended Mendel's work on rules of genetic inheritance. No later than 1907, he discovered the principle of genetic equilibrium of alleles (different versions of a gene) within a population that was later rediscovered by the British mathematician G. H. Hardy. See Fig. 2.12. English-language science books have tended to credit Hardy and not Weinberg's earlier work, or at most to call it the Hardy-Weinberg principle.

Theodor Boveri (German, 1862–1915) had an enormously productive and underrated scientific career. He discovered and named the centrosome that guides chromosomes apart when a nucleus divides. He also demonstrated that proper embryonic development requires the presence of the normal number of chromosomes for a given species. He made many important discoveries regarding the role of mutations to the chromosomes in causing cancer.

Karl Correns (German, 1864–1933) was another scientist who rediscovered and extended Mendel's work on rules of genetic inheritance. In addition, he found that plant cells inherit their properties not only from genes in the nucleus, but also from genes in chloroplasts and mitochondria.

Phoebus Levene (Baltic Jewish, 1869–1940) worked with Albrecht Kossel and Hermann Emil Fischer. He continued and extended Kossel's research on the chemical composition and structure of DNA and RNA.

Erich Tschermak von Seysenegg (Austrian, 1871–1962) also rediscovered and extended Mendel's work on rules of genetic inheritance.

Hans Winkler (German, 1877–1945) described the total inheritance of a cell by combining the words gene and chromosome to create a new word, "genome," in 1920. He also introduced the new word "heteroploid" to describe an abnormal number of chromosomes.

Richard Goldschmidt (German, 1878–1958) made many contributions in the fields of genetics, evolution, and developmental biology.

Charlotte Auerbach (German, 1899–1994) pioneered the study of the chemical mutagenesis of DNA. Among other discoveries, she found that mustard gas could cause mutations and therefore could be carcinogenic in addition to its dangerous corrosive effects on organisms.

Curt Stern (German, 1902–1981) demonstrated homologous recombination or crossing over between chromosomes in fruit flies and spent much of his career focusing on human genetics and its implications for medicine.

In the early 1930s, Alfred Kühn (German, 1885–1968) and Adolf Butenandt (German, 1903–1995) led a closely knit research community that induced and analyzed mutations in insects and other species, and used that data to demonstrate that individual genes produce individual proteins (sometimes called the "one gene, one enzyme hypothesis") [Egelhaaf 1996; Grossbach 1996, 2009]. Some other key members of the same research community included:

- Hans Bauer (German, 1904–1988)
- Erich Becker (German, 19??–1942)
- Ernst Caspari (German, 1909–1988)
- Helmut Döring (German, 19??–1942)
- Georg Gottschewski (German, 1906–1975)
- Karl Henke (German, 1895–1956)
- Paula Hertwig (German, 1889–1983, daughter of Oscar Hertwig)
- Lothar Löffler (German, 1901–1983) chemical and radiation-induced mutations in invertebrates and vertebrates
- Karl Pirschle (German, 1900–1945)
- Ernst Plagge (German, 1911–1945)
- Hans Stubbe (German, 1902–1989)

See Figs. 2.13–2.14. Unfortunately, several members of that genetics research community had to flee to other countries in the 1930s to escape antisemitism and political repression. Other members were drafted into the military after the war started, and several died in the war. Thus this particular research community had largely ceased to function by around 1940.

By using the publications by Alfred Kühn and the others as a roadmap, the U.S. scientists George Beadle and Edward Tatum later demonstrated the same "one gene, one enzyme" principle; for that work they won the 1958 Nobel Prize in Physiology or Medicine and are prominently discussed in most modern genetics textbooks. All of the earlier research by Alfred Kühn and other German-speaking scientists was essentially ignored, and they have been largely forgotten.

In a revolutionary 1935 paper (Fig. 2.15), Max Delbrück (German, 1906–1981), Nikolai Timoféeff-Ressovsky (Russian but worked in Germany 1925–1945, lived 1900–1981), and Karl Günter Zimmer (German, 1911–1988) at the Kaiser Wilhelm Society in Berlin described and demonstrated the structure of chromosomal DNA, methods and consequences of inducing point mutations in DNA, and forced genetic recombination of different pieces of DNA [Ernst Fischer 1988; Segrè 2011; Sloan and Fogel 2011; Timoféeff-Ressovsky, Zimmer, and Delbrück 1935]. The methods and objectives that Timoféeff-Ressovsky, Zimmer, and Delbrück stated at the beginning of their paper essentially defined the new field of molecular biology [Sloan and Fogel 2011, p. 222]:

> In the following paper, we attempt to construct a general picture of the nature of the gene and of mutation, on the basis of experimental investigations of the mutation processes in *Drosophila* and a physical analysis of the results of those experiments. Compared to previous hypotheses about the nature of the gene and of gene mutation, we believe we have taken a step forward, in that our ideas are constructed only from the experimental results of mutation research, and therefore from an area of research that concerns events directly involving the genes themselves. [...]
>
> Thus, we hope to arrive at a theory of the mutation process and gene structure that will be experimentally well-founded and that will have experimentally verifiable implications. Of course, we are far from regarding our ideas as conclusive; rather, we see their value lying in the extending of earlier approaches through the use of the concepts of physics.
>
> This paper represents a collaboration between genetics and physics.

Erwin Chargaff (Austrian, 1905–2002) made many experimental measurements of the chemical composition of DNA and discovered guanine-cytosine (G-C) and adenine-thymine (A-T) base-pairing, which was critical for working out the correct structure of double-stranded DNA.

As shown in Fig. 2.16, in 1940 (under wartime conditions and 13 years before the discovery by Rosalind Franklin, Francis Crick, and James Watson), Hans Friedrich-Freksa (German, 1906–1973) proposed a double-stranded self-complementary model of DNA structure and replication [Friedrich-Freksa 1940]. Apparently the war prevented him from taking that work even further.

By 1942, despite even more severe wartime hindrances, Gerhard Schramm (German, 1910–1969) identified the genome of the tobacco mosaic virus as RNA, showed that its protein subunits are identical, and mutated the RNA to create mutant proteins.[5] See Fig. 2.17.

---

[5] Schramm 1941; Schramm 1943; Schramm and Dannenberg 1944; Schramm and Müller 1940; Schramm and Müller 1942; Schramm and Rebensburg 1942.

George Gamow (Russian but educated and worked in Germany, lived 1904–1968) made several insightful proposals and worked with other scientists to determine the genetic code, the rules for what sequences of DNA or RNA nucleotides tell cells to produce what sequences of amino acids in proteins [Segrè 2011].

J. Heinrich Matthaei (German, 1929–) also played a major role in deciphering the genetic code. In 1961, he demonstrated that a synthetic poly-uridine RNA made cells produce a poly-phenylalanine protein, so the RNA sequence UUU codes for a phenylalanine amino acid. After that initial breakthrough, Matthaei continued to decipher parts of the genetic code.

Heinz-Günter Wittmann (German, 1927–1990) made a number of important discoveries regarding the genetic code, ribosomes, the proteome of *E. coli*, and other aspects of genetics and genomics.

Werner Arber (Swiss, 1929–) harnessed natural DNA restriction enzymes to cut and splice DNA, for which he won the Nobel Prize in Physiology or Medicine in 1978. Professor Peter Reichard of the Karolinska Medico-Chirurgical Institute explained the importance of Arber's innovations [https://www.nobelprize.org/prizes/medicine/1978/ceremony-speech/]:

> We can compare the DNA of a single human cell with a book containing all the information for the development and function of the cell. [...]
>
> Restriction enzymes are the tools which make it possible to open the sealed book. Werner Arber discovered these enzymes in the early 1960s when he analyzed an apparently obscure phenomenon in bacteria, discovered 10 years earlier by Bertani and Weigle, called host-controlled modification. In a series of simple but elegant experiments Arber showed that this phenomenon was caused by a change in DNA and apparently served to protect the host from foreign genes. Foreign DNA is degraded, and Arber postulated that bacteria contain restriction enzymes with the capacity to recognize and bind to recurring structural elements of DNA. At these locations the DNA-helix is severed: the pages of the book are separated. [...]
>
> The application of restriction enzymes has revolutionized the genetics of higher organisms and completely changed our ideas of the organisation of their genes. In contrast to the DNA of bacteria, the DNA of higher organisms is not a contiguous structure coding for one protein. Instead, genes contain "quiet" regions alternating with regions containing the genetic code. Restriction enzymes have also been used for genetic engineering. With their aid we can selectively remove parts of the genetic material and transplant genes into a foreign background. In this way genes from higher organisms have been transferred to bacteria, and in certain cases such bacteria can be used to produce human hormones. In the near future we can expect many products of medical importance to be synthesized.

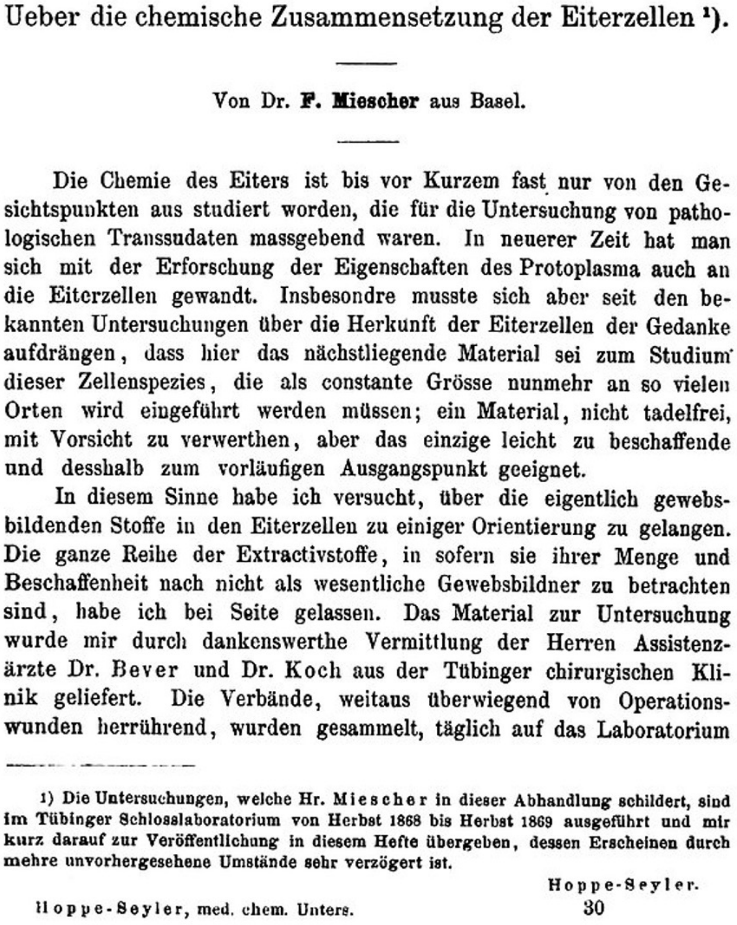
***Medicinisch-chemische Untersuchungen* 4:441–460 (1871)**



Ueber die chemische Zusammensetzung der Eiterzellen 1).

Von Dr. **F. Miescher** aus Basel.

Die Chemie des Eiters ist bis vor Kurzem fast nur von den Gesichtspunkten aus studiert worden, die für die Untersuchung von pathologischen Transsudaten massgebend waren. In neuerer Zeit hat man sich mit der Erforschung der Eigenschaften des Protoplasma auch an die Eiterzellen gewandt. Insbesondre musste sich aber seit den bekannten Untersuchungen über die Herkunft der Eiterzellen der Gedanke aufdrängen, dass hier das nächstliegende Material sei zum Studium dieser Zellenspezies, die als constante Grösse nunmehr an so vielen Orten wird eingeführt werden müssen; ein Material, nicht tadelfrei, mit Vorsicht zu verwerthen, aber das einzige leicht zu beschaffende und desshalb zum vorläufigen Ausgangspunkt geeignet.

In diesem Sinne habe ich versucht, über die eigentlich gewebsbildenden Stoffe in den Eiterzellen zu einiger Orientierung zu gelangen. Die ganze Reihe der Extractivstoffe, in sofern sie ihrer Menge und Beschaffenheit nach nicht als wesentliche Gewebsbildner zu betrachten sind, habe ich bei Seite gelassen. Das Material zur Untersuchung wurde mir durch dankenswerthe Vermittlung der Herren Assistenzärzte Dr. Bever und Dr. Koch aus der Tübinger chirurgischen Klinik geliefert. Die Verbände, weitaus überwiegend von Operationswunden herrührend, wurden gesammelt, täglich auf das Laboratorium

---

1) Die Untersuchungen, welche Hr. Miescher in dieser Abhandlung schildert, sind im Tübinger Schlosslaboratorium von Herbst 1868 bis Herbst 1869 ausgeführt und mir kurz darauf zur Veröffentlichung in diesem Hefte übergeben, dessen Erscheinen durch mehre unvorhergesehene Umstände sehr verzögert ist.

Hoppe-Seyler.

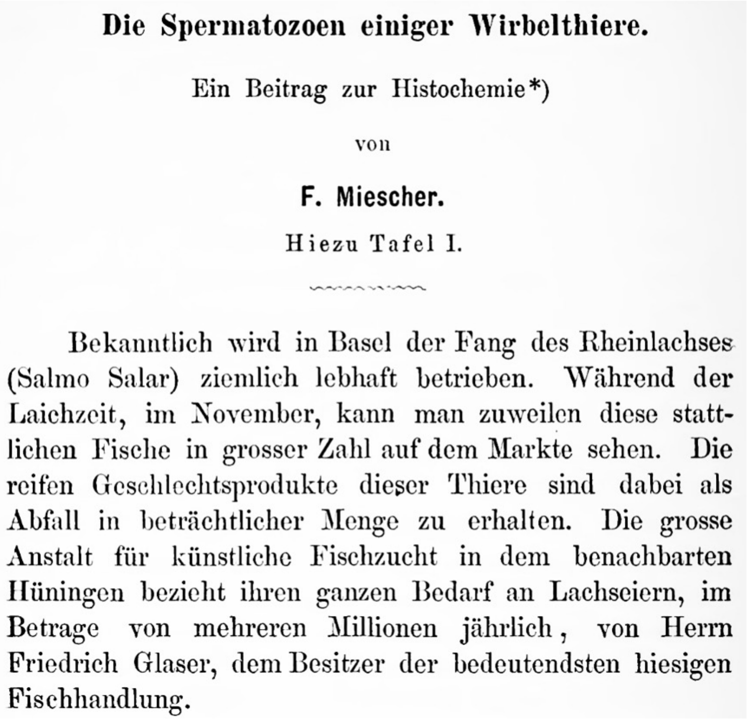
Johannes Friedrich Miescher (1844–1895) extracted and purified DNA from human white blood cells and proposed that DNA is involved in heredity (1868–1869).



Die Spermatozoen einiger Wirbelthiere.

Ein Beitrag zur Histochemie*)

von

F. Miescher.

Hiezu Tafel I.

Bekanntlich wird in Basel der Fang des Rheinlachses (Salmo Salar) ziemlich lebhaft betrieben. Während der Laichzeit, im November, kann man zuweilen diese stattlichen Fische in grosser Zahl auf dem Markte sehen. Die reifen Geschlechtsprodukte dieser Thiere sind dabei als Abfall in beträchtlicher Menge zu erhalten. Die grosse Anstalt für künstliche Fischzucht in dem benachbarten Hüningen bezieht ihren ganzen Bedarf an Lachseiern, im Betrage von mehreren Millionen jährlich, von Herrn Friedrich Glaser, dem Besitzer der bedeutendsten hiesigen Fischhandlung.

I.

(Hierzu Taf. XV—XVIII.)

Die Arbeiten, über deren ersten Theil ich hier berichte, wollen im Ganzen den einfachen Plan verfolgen, die Eigenschaften der Zelle an einer Reihe verschieden gewählter Objecte zu prüfen, welche die Möglichkeit bieten das mikroskopische Bild des lebenden Zustandes mit dem conservirten und gefärbten Präparat zu vergleichen. Hätte ich, wie es anfangs die Absicht war, erst nach Durcharbeitung des ganzen Planes die Resultate mittheilen wollen,

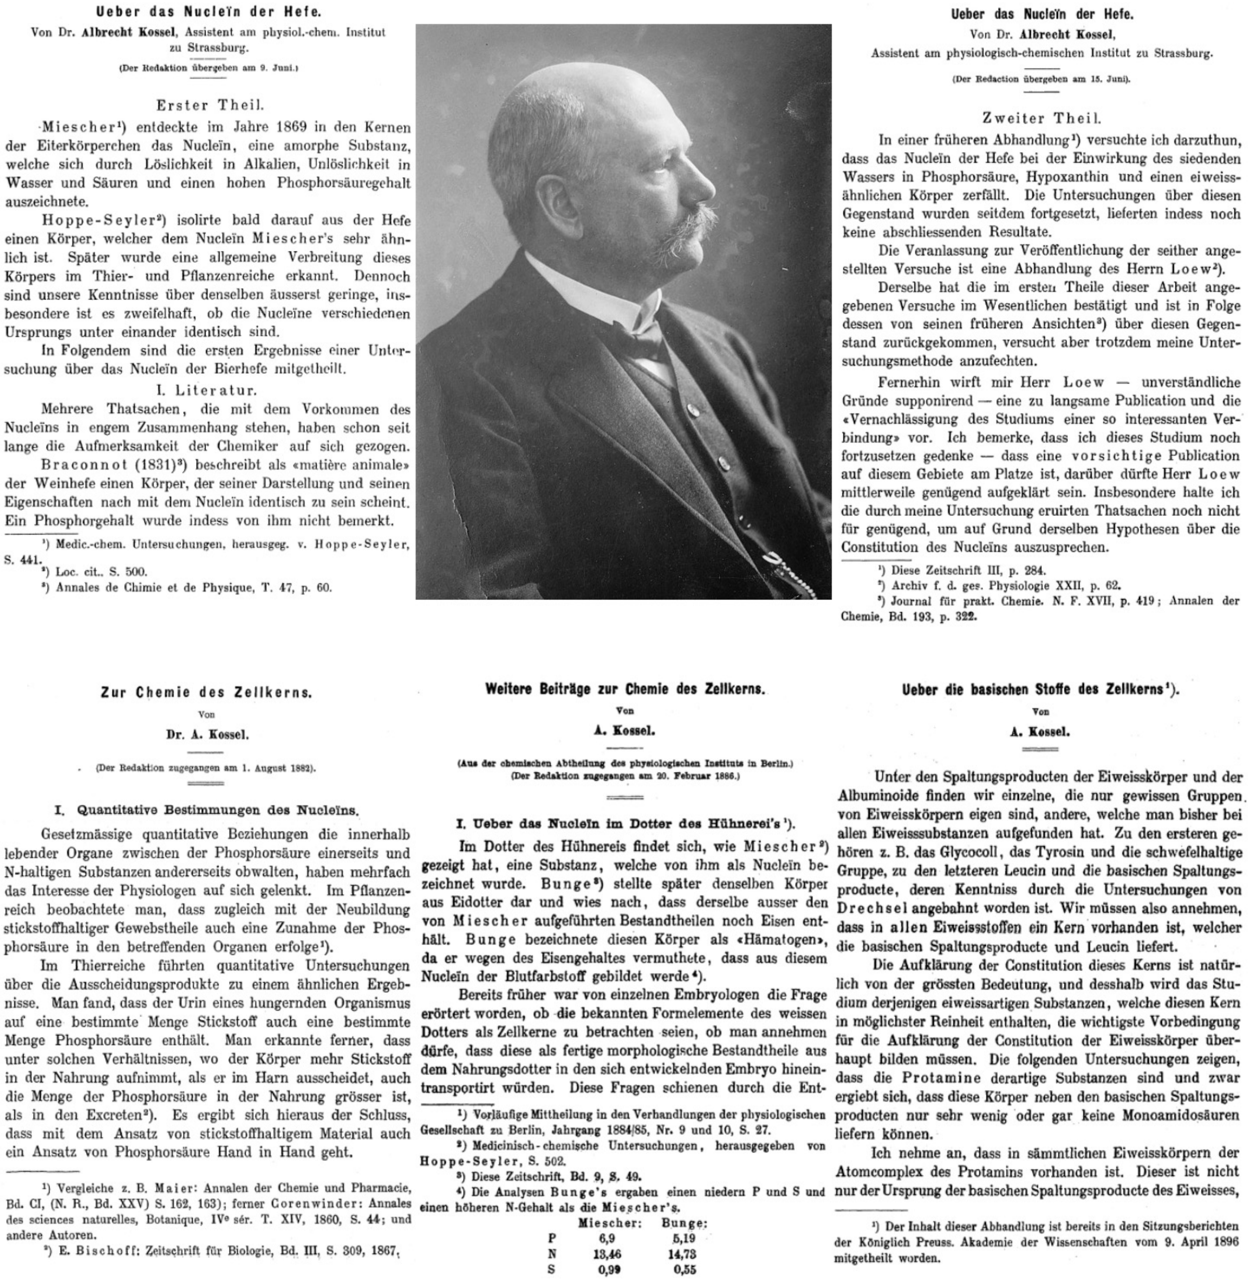
Figure 2.10: Walther Flemming made detailed observations of chromosomes during mitotic cell division from 1873 onward.

Beginning in the 1870s, Albrecht Kossel (1853–1927) showed that DNA and RNA contain five different bases (adenine, cytosine, guanine, thymine, and uracil), demonstrated that those bases are connected via linkages of sugars and phosphates, and isolated and studied proteins that bind to nucleic acids in the nucleus (histones and other accessory proteins). He won the 1910 Nobel Prize in Physiology or Medicine.



Ueber das Nucleïn der Hefe.

Von Dr. **Albrecht Kossel**, Assistent am physiol.-chem. Institut zu Strassburg.

(Der Redaktion übergeben am 9. Juni.)

Erster Theil.

Miescher[1] entdeckte im Jahre 1869 in den Kernen der Eiterkörperchen das Nucleïn, eine amorphe Substanz, welche sich durch Löslichkeit in Alkalien, Unlöslichkeit in Wasser und Säuren und einen hohen Phosphorsäuregehalt auszeichnete.

Hoppe-Seyler[2] isolirte bald darauf aus der Hefe einen Körper, welcher dem Nucleïn Miescher's sehr ähnlich ist. Später wurde eine allgemeine Verbreitung dieses Körpers im Thier- und Pflanzenreiche erkannt. Dennoch sind unsere Kenntnisse über denselben äusserst geringe, insbesondere ist es zweifelhaft, ob die Nucleïne verschiedenen Ursprungs unter einander identisch sind.

In Folgendem sind die ersten Ergebnisse einer Untersuchung über das Nucleïn der Bierhefe mitgetheilt.

I. Literatur.

Mehrere Thatsachen, die mit dem Vorkommen des Nucleïns in engem Zusammenhang stehen, haben schon seit lange die Aufmerksamkeit der Chemiker auf sich gezogen.

Braconnot (1831)[3] beschreibt als «matière animale» der Weinhefe einen Körper, der seiner Darstellung und seinen Eigenschaften nach mit dem Nucleïn identisch zu sein scheint. Ein Phosphorgehalt wurde indess von ihm nicht bemerkt.

Ueber das Nucleïn der Hefe.

Von Dr. **Albrecht Kossel**,
Assistent am physiologisch-chemischen Institut zu Strassburg.

(Der Redaction übergeben am 15. Juni).

Zweiter Theil.

In einer früheren Abhandlung[1] versuchte ich darzuthun, dass das Nucleïn der Hefe bei der Einwirkung des siedenden Wassers in Phosphorsäure, Hypoxanthin und einen eiweissähnlichen Körper zerfällt. Die Untersuchungen über diesen Gegenstand wurden seitdem fortgesetzt, lieferten indess noch keine abschliessenden Resultate.

Die Veranlassung zur Veröffentlichung der seither angestellten Versuche ist eine Abhandlung des Herrn Loew[2].

Derselbe hat die im ersten Theile dieser Arbeit angegebenen Versuche im Wesentlichen bestätigt und ist in Folge dessen von seinen früheren Ansichten[3] über diesen Gegenstand zurückgekommen, versucht aber trotzdem meine Untersuchungsmethode anzufechten.

Fernerhin wirft mir Herr Loew — unverständliche Gründe supponirend — eine zu langsame Publication und die «Vernachlässigung des Studiums einer so interessanten Verbindung» vor. Ich bemerke, dass ich dieses Studium noch fortzusetzen gedenke — dass eine vorsichtige Publication auf diesem Gebiete am Platze ist, darüber dürfte Herr Loew mittlerweile genügend aufgeklärt sein. Insbesondere halte ich die durch meine Untersuchung eruirten Thatsachen noch nicht für genügend, um auf Grund derselben Hypothesen über die Constitution des Nucleïns auszusprechen.

Zur Chemie des Zellkerns.

Von

Dr. A. Kossel.

(Der Redaktion zugegangen am 1. August 1882).

I. Quantitative Bestimmungen des Nucleïns.

Gesetzmässige quantitative Beziehungen die innerhalb lebender Organe zwischen der Phosphorsäure einerseits und N-haltigen Substanzen andererseits obwalten, haben mehrfach das Interesse der Physiologen auf sich gelenkt. Im Pflanzenreich beobachtete man, dass zugleich mit der Neubildung stickstoffhaltiger Gewebstheile auch eine Zunahme der Phosphorsäure in den betreffenden Organen erfolge[1].

Im Thierreiche führten quantitative Untersuchungen über die Ausscheidungsprodukte zu einem ähnlichen Ergebnisse. Man fand, dass der Urin eines hungernden Organismus auf eine bestimmte Menge Stickstoff auch eine bestimmte Menge Phosphorsäure enthält. Man erkannte ferner, dass unter solchen Verhältnissen, wo der Körper mehr Stickstoff in der Nahrung aufnimmt, als er im Harn ausscheidet, auch die Menge der Phosphorsäure in der Nahrung grösser ist, als in den Excreten[2]. Es ergibt sich hieraus der Schluss, dass mit dem Ansatz von stickstoffhaltigem Material auch ein Ansatz von Phosphorsäure Hand in Hand geht.

Weitere Beiträge zur Chemie des Zellkerns.

Von

A. Kossel.

(Aus der chemischen Abtheilung des physiologischen Instituts in Berlin.)
(Der Redaktion zugegangen am 20. Februar 1886.)

I. Ueber das Nucleïn im Dotter des Hühnerei's[1].

Im Dotter des Hühnereis findet sich, wie Miescher[2] gezeigt hat, eine Substanz, welche von ihm als Nucleïn bezeichnet wurde. Bunge[3] stellte später denselben Körper aus Eidotter dar und wies nach, dass derselbe ausser den von Miescher aufgeführten Bestandtheilen noch Eisen enthält. Bunge bezeichnete diesen Körper als «Hämatogen», da er wegen des Eisengehaltes vermuthete, dass aus diesem Nucleïn der Blutfarbstoff gebildet werde[4].

Bereits früher war von einzelnen Embryologen die Frage erörtert worden, ob die bekannten Formelemente des weissen Dotters als Zellkerne zu betrachten seien, ob man annehmen dürfe, dass diese als fertige morphologische Bestandtheile aus dem Nahrungsdotter in den sich entwickelnden Embryo hineintransportirt würden. Diese Fragen schienen durch die Ent-

Ueber die basischen Stoffe des Zellkerns[1].

Von

A. Kossel.

Unter den Spaltungsproducten der Eiweisskörper und der Albuminoide finden wir einzelne, die nur gewissen Gruppen von Eiweisskörpern eigen sind, andere, welche man bisher bei allen Eiweisssubstanzen aufgefunden hat. Zu den ersteren gehören z. B. das Glycocoll, das Tyrosin und die schwefelhaltige Gruppe, zu den letzteren Leucin und die basischen Spaltungsproducte, deren Kenntniss durch die Untersuchungen von Drechsel angebahnt worden ist. Wir müssen also annehmen, dass in allen Eiweissstoffen ein Kern vorhanden ist, welcher die basischen Spaltungsproducte und Leucin liefert.

Die Aufklärung der Constitution dieses Kerns ist natürlich von der grössten Bedeutung, und desshalb wird das Studium derjenigen eiweissartigen Substanzen, welche diesen Kern in möglichster Reinheit enthalten, die wichtigste Vorbedingung für die Aufklärung der Constitution der Eiweisskörper überhaupt bilden müssen. Die folgenden Untersuchungen zeigen, dass die Protamine derartige Substanzen sind und zwar ergiebt sich, dass diese Körper neben den basischen Spaltungsproducten nur sehr wenig oder gar keine Monoamidosäuren liefern können.

Ich nehme an, dass in sämmtlichen Eiweisskörpern der Atomcomplex des Protamins vorhanden ist. Dieser ist nicht nur der Ursprung der basischen Spaltungsproducte des Eiweisses,

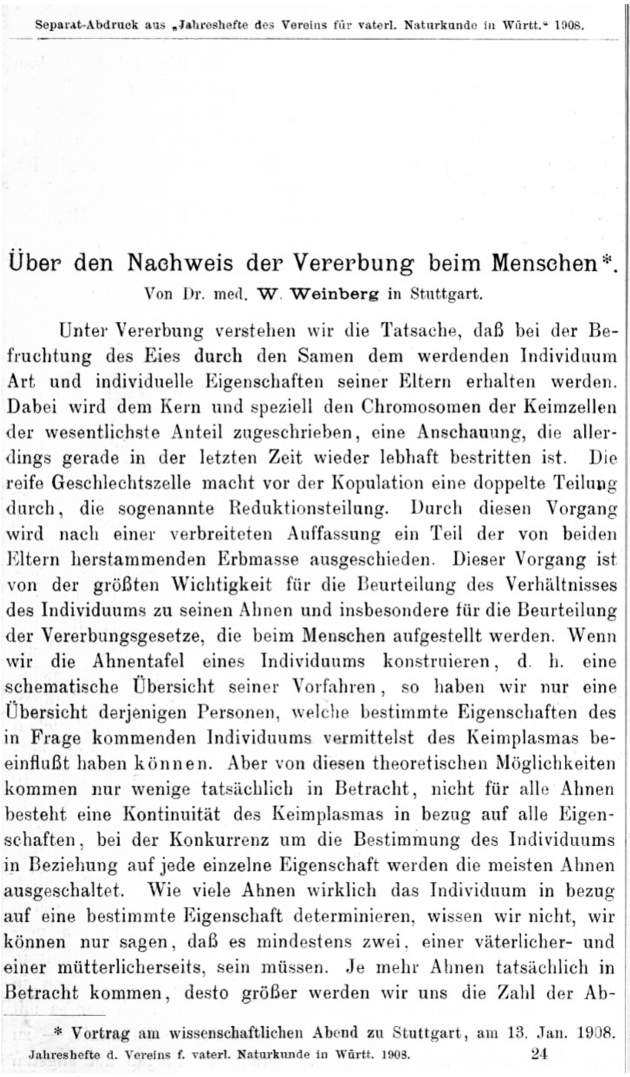
Wilhelm Weinberg
(1862–1937)

Discovered the equilibrium distribution of alleles (different versions of a gene) within a population (1907 or earlier)

***Jahreshefte des Vereins für vaterländische Naturkunde in Württemberg* 64:369–382 (1908)**



Separat-Abdruck aus „Jahreshefte des Vereins für vaterl. Naturkunde in Württ." 1908.

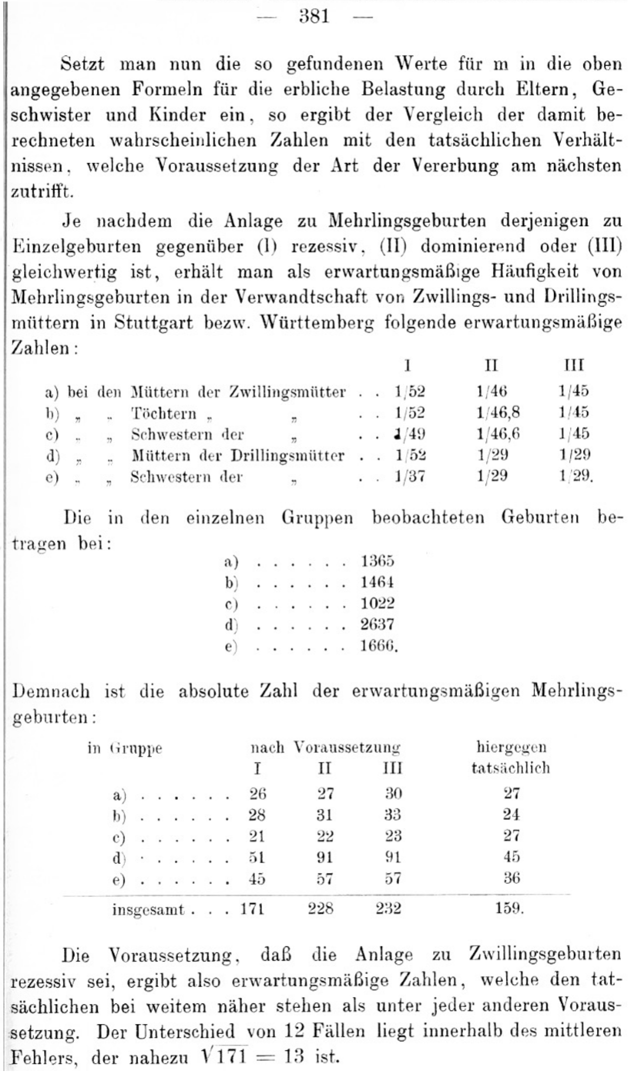
Über den Nachweis der Vererbung beim Menschen*.

Von Dr. med. **W. Weinberg** in Stuttgart.

Unter Vererbung verstehen wir die Tatsache, daß bei der Befruchtung des Eies durch den Samen dem werdenden Individuum Art und individuelle Eigenschaften seiner Eltern erhalten werden. Dabei wird dem Kern und speziell den Chromosomen der Keimzellen der wesentlichste Anteil zugeschrieben, eine Anschauung, die allerdings gerade in der letzten Zeit wieder lebhaft bestritten ist. Die reife Geschlechtszelle macht vor der Kopulation eine doppelte Teilung durch, die sogenannte Reduktionsteilung. Durch diesen Vorgang wird nach einer verbreiteten Auffassung ein Teil der von beiden Eltern herstammenden Erbmasse ausgeschieden. Dieser Vorgang ist von der größten Wichtigkeit für die Beurteilung des Verhältnisses des Individuums zu seinen Ahnen und insbesondere für die Beurteilung der Vererbungsgesetze, die beim Menschen aufgestellt werden. Wenn wir die Ahnentafel eines Individuums konstruieren, d. h. eine schematische Übersicht seiner Vorfahren, so haben wir nur eine Übersicht derjenigen Personen, welche bestimmte Eigenschaften des in Frage kommenden Individuums vermittelst des Keimplasmas beeinflußt haben können. Aber von diesen theoretischen Möglichkeiten kommen nur wenige tatsächlich in Betracht, nicht für alle Ahnen besteht eine Kontinuität des Keimplasmas in bezug auf alle Eigenschaften, bei der Konkurrenz um die Bestimmung des Individuums in Beziehung auf jede einzelne Eigenschaft werden die meisten Ahnen ausgeschaltet. Wie viele Ahnen wirklich das Individuum in bezug auf eine bestimmte Eigenschaft determinieren, wissen wir nicht, wir können nur sagen, daß es mindestens zwei, einer väterlicher- und einer mütterlicherseits, sein müssen. Je mehr Ahnen tatsächlich in Betracht kommen, desto größer werden wir uns die Zahl der Ab-

---

* Vortrag am wissenschaftlichen Abend zu Stuttgart, am 13. Jan. 1908.



Setzt man nun die so gefundenen Werte für m in die oben angegebenen Formeln für die erbliche Belastung durch Eltern, Geschwister und Kinder ein, so ergibt der Vergleich der damit berechneten wahrscheinlichen Zahlen mit den tatsächlichen Verhältnissen, welche Voraussetzung der Art der Vererbung am nächsten zutrifft.

Je nachdem die Anlage zu Mehrlingsgeburten derjenigen zu Einzelgeburten gegenüber (I) rezessiv, (II) dominierend oder (III) gleichwertig ist, erhält man als erwartungsmäßige Häufigkeit von Mehrlingsgeburten in der Verwandtschaft von Zwillings- und Drillingsmüttern in Stuttgart bezw. Württemberg folgende erwartungsmäßige Zahlen:

	I	II	III
a) bei den Müttern der Zwillingsmütter . .	1/52	1/46	1/45
b) „ „ Töchtern „ „ . .	1/52	1/46,8	1/45
c) „ „ Schwestern der „ . .	1/49	1/46,6	1/45
d) „ „ Müttern der Drillingsmütter . .	1/52	1/29	1/29
e) „ „ Schwestern der „ . .	1/37	1/29	1/29.

Die in den einzelnen Gruppen beobachteten Geburten betragen bei:

a)	1365
b)	1464
c)	1022
d)	2637
e)	1666.

Demnach ist die absolute Zahl der erwartungsmäßigen Mehrlingsgeburten:

in Gruppe	nach Voraussetzung			hiergegen
	I	II	III	tatsächlich
a)	26	27	30	27
b)	28	31	33	24
c)	21	22	23	27
d)	51	91	91	45
e)	45	57	57	36
insgesamt . . .	171	228	232	159.

Die Voraussetzung, daß die Anlage zu Zwillingsgeburten rezessiv sei, ergibt also erwartungsmäßige Zahlen, welche den tatsächlichen bei weitem näher stehen als unter jeder anderen Voraussetzung. Der Unterschied von 12 Fällen liegt innerhalb des mittleren Fehlers, der nahezu $\sqrt{171} = 13$ ist.

a. Heteroploidien.
b. Polyploidien.
C. Kombinationen.

Auf Abb. 1 sind die wichtigsten Typen der genotypischen Erbänderungen schematisch dargestellt.

Weiterhin sollen uns nur die Genmutationen interessieren. Über Letztere erhalten wir aus dem spontanen Mutationsprozeß auch schon einige Angaben. Es hat sich gezeigt, daß Genmutationen immer herterozygot auftreten, d. h., daß nur eins von den zwei im diploiden Organismus vorhandenen Allelen im Moment der Mutationsentstehung sich verändert. Weiterhin zeigte es sich, daß durch Mutationen dominante und rezessive Eigenschaften, verschiedenste morphologische Merkmale und physiologische Eigenschaften, sehr

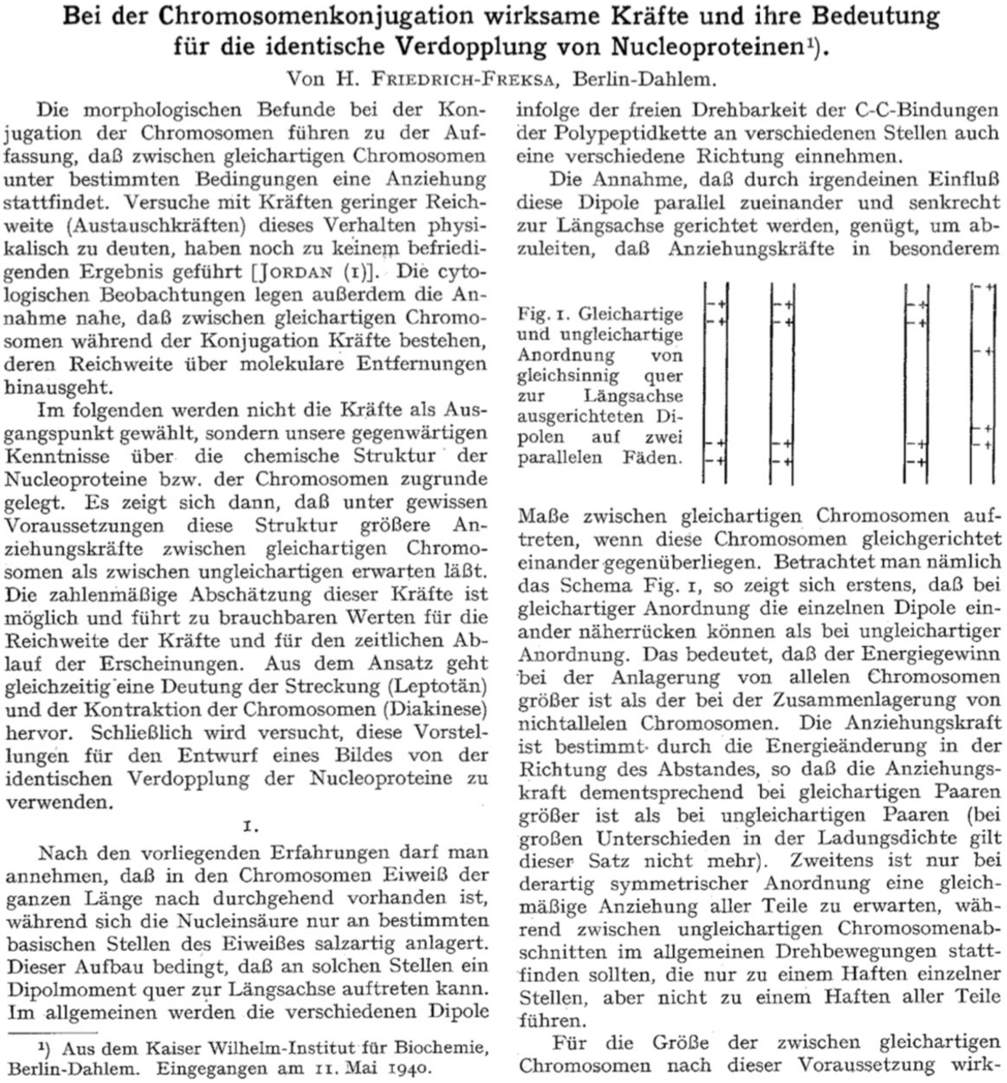
Abb. 1. Verschiedene Typen von Mutationen. A. Genmutationen: das dominante „normale“ (oder Ausgangs-) Allel A mutiert zu a; das rezessive Allel b' mutiert zu B'; das dominante Allel C ergibt durch Mutation c^1 oder c^2 (multiple Allele). B. Chromosomenmutationen: a. Wegfall eines Chromosomenstücks; b. Deletion; c. Inversion; d. einfache Translokation; e. gegenseitige Translokation. C. Genommutationen: a. normaler haploider Chromosomensatz; b.—c. Heteroploidie (b. - Haplosomie, c. - Trisomie); d. Polyploidie.

Figure 2.15: In 1935, Max Delbrück, Nikolai Timoféeff-Ressovsky, and Karl Günter Zimmer published a detailed and advanced paper on chromosomes and gene structures, as well as methods and effects of mutating or recombining them [Timoféeff-Ressovsky, Zimmer, and Delbrück 1935].

Hans Friedrich-Freksa
(1906–1973)

Proposed that the structure of DNA is double-stranded with electrostatic attraction between complementary sequences

Die Naturwissenschaften
28:24:376–379 (1940)



Bei der Chromosomenkonjugation wirksame Kräfte und ihre Bedeutung für die identische Verdopplung von Nucleoproteinen[1]).

Von H. Friedrich-Freksa, Berlin-Dahlem.

Die morphologischen Befunde bei der Konjugation der Chromosomen führen zu der Auffassung, daß zwischen gleichartigen Chromosomen unter bestimmten Bedingungen eine Anziehung stattfindet. Versuche mit Kräften geringer Reichweite (Austauschkräften) dieses Verhalten physikalisch zu deuten, haben noch zu keinem befriedigenden Ergebnis geführt [Jordan (1)]. Die cytologischen Beobachtungen legen außerdem die Annahme nahe, daß zwischen gleichartigen Chromosomen während der Konjugation Kräfte bestehen, deren Reichweite über molekulare Entfernungen hinausgeht.

Im folgenden werden nicht die Kräfte als Ausgangspunkt gewählt, sondern unsere gegenwärtigen Kenntnisse über die chemische Struktur der Nucleoproteine bzw. der Chromosomen zugrunde gelegt. Es zeigt sich dann, daß unter gewissen Voraussetzungen diese Struktur größere Anziehungskräfte zwischen gleichartigen Chromosomen als zwischen ungleichartigen erwarten läßt. Die zahlenmäßige Abschätzung dieser Kräfte ist möglich und führt zu brauchbaren Werten für die Reichweite der Kräfte und für den zeitlichen Ablauf der Erscheinungen. Aus dem Ansatz geht gleichzeitig eine Deutung der Streckung (Leptotän) und der Kontraktion der Chromosomen (Diakinese) hervor. Schließlich wird versucht, diese Vorstellungen für den Entwurf eines Bildes von der identischen Verdopplung der Nucleoproteine zu verwenden.

I.

Nach den vorliegenden Erfahrungen darf man annehmen, daß in den Chromosomen Eiweiß der ganzen Länge nach durchgehend vorhanden ist, während sich die Nucleinsäure nur an bestimmten basischen Stellen des Eiweißes salzartig anlagert. Dieser Aufbau bedingt, daß an solchen Stellen ein Dipolmoment quer zur Längsachse auftreten kann. Im allgemeinen werden die verschiedenen Dipole infolge der freien Drehbarkeit der C-C-Bindungen der Polypeptidkette an verschiedenen Stellen auch eine verschiedene Richtung einnehmen.

Die Annahme, daß durch irgendeinen Einfluß diese Dipole parallel zueinander und senkrecht zur Längsachse gerichtet werden, genügt, um abzuleiten, daß Anziehungskräfte in besonderem Maße zwischen gleichartigen Chromosomen auftreten, wenn diese Chromosomen gleichgerichtet einander gegenüberliegen. Betrachtet man nämlich das Schema Fig. 1, so zeigt sich erstens, daß bei gleichartiger Anordnung die einzelnen Dipole einander näherrücken können als bei ungleichartiger Anordnung. Das bedeutet, daß der Energiegewinn bei der Anlagerung von allelen Chromosomen größer ist als der bei der Zusammenlagerung von nichtallelen Chromosomen. Die Anziehungskraft ist bestimmt durch die Energieänderung in der Richtung des Abstandes, so daß die Anziehungskraft dementsprechend bei gleichartigen Paaren größer ist als bei ungleichartigen Paaren (bei großen Unterschieden in der Ladungsdichte gilt dieser Satz nicht mehr). Zweitens ist nur bei derartig symmetrischer Anordnung eine gleichmäßige Anziehung aller Teile zu erwarten, während zwischen ungleichartigen Chromosomenabschnitten im allgemeinen Drehbewegungen stattfinden sollten, die nur zu einem Haften einzelner Stellen, aber nicht zu einem Haften aller Teile führen.

Für die Größe der zwischen gleichartigen Chromosomen nach dieser Voraussetzung wirk-

Fig. 1. Gleichartige und ungleichartige Anordnung von gleichsinnig quer zur Längsachse ausgerichteten Dipolen auf zwei parallelen Fäden.

Über einige Mutationen des Tabakmosaikvirus und eine „Parallelmutation" des Tomatenmosaikvirus[*].

Es ist bekannt, daß im Verlauf der Vermehrung des Tabakmosaikvirus in Pflanzen Mutationen zu neuen, konstanten Stämmen auftreten[1–7]. In einigen Fällen kann man das Auftreten solcher Mutationen direkt am Erscheinen von in die normale Hellgrün-Dunkelgrün-Fleckung eingesprengten, scharf abgegrenzten „gelben Flecken" erkennen. Aus solchen Flecken lassen sich die mehrfach beschriebenen „Gelbstämme" des Tabakmosaikvirus isolieren und vermehren.

Ein in unserem Versuchsmaterial spontan aufgetretener Gelbstamm wurde in Anlehnung an die von F. O. Holmes[8] vorgeschlagenen Bezeichnungen, die für das normale TM. den Namen *Marmor tabaci* var. *vulgare* vorsehen, als var. *flavum* bezeichnet. Er ruft auf *Nicotiana tabacum* „Samsun" primär gelbliche Flecken hervor; das frühe Sekundärsymptom ist durch eine besonders kräftige Aufhellung des Gewebes um die Adern gekennzeichnet, die nächstjüngeren Blätter bleichen fast völlig aus, und später entwickelt sich bei gegenüber normalem TM. viel stärkerer Wachstumshemmung der ganzen Pflanze und mehr oder weniger starken Blattdeformationen eine Gelb-Grün-Marmorierung (Fig. 1c).

Bekannt sind auch Mutationen des TM. zu abgeschwächter Symptomausbildung. Ein von uns als var. *tenue* bezeichneter Stamm wurde aus Reibsaft von mit normalem TM. infizierten Pflanzen, die bei hoher Temperatur (34° C) kultiviert waren, über einen Einzelherd auf *Nicotiana glutinosa* isoliert. Auf *Nicotiana tabacum* „Samsun" fehlen wie beim normalen TM. primäre Symptome. Die Sekundärsymptome treten verzögert auf und bleiben schwächer. Die Fleckung beschränkt sich auf dunkler grüne Gewebepartien um die Adern und hellgrüne Zwischenfelder. Blattdeformationen fehlen (Fig. 1d).

Auf einer an diesem Symptom erkrankten Pflanze trat ein heller Fleck auf. Abimpfungen von diesem Fleck führten zu einem als var. *necroticum* bezeichneten Stamm, der ähnliche Symptome wie var. *tenue* auslöst, aber regelmäßig auf den dem primär infizierten Blatt folgenden Blättern kleine, helle nekrotische Flecken erzeugt (Fig. 1e).

In einer früheren Veröffentlichung[9] wurde als „Tomatenmosaikvirus Dahlem 1940" ein dem Tabakmosaikvirus sehr nahe verwandtes Virus beschrieben und biologisch, chemisch und elektronenmikroskopisch näher charakterisiert. Auf Samsun-Tabak erzeugt dieses Virus ein noch schwächeres Sekundärsymptom als *M. tabaci* var. *tenue* (Fig. 1f). Es unterscheidet sich von normalem TM. und den bisher hier erwähnten Stämmen qualitativ dadurch, daß es auf „Java"-Tabak und *Nicotiana silvestris* nekrotische Primärsymptome erzeugt, während auf *Phaseolus vulgaris* solche ausbleiben. Um die enge Verwandtschaft dieses Virus mit TM. anzudeuten, es aber doch deutlich von den als Mutationen direkt beobachteten Stämmen abzusetzen, wäre es den Nomenklaturvorschlägen von Holmes folgend als *M. tabaci* subspec. *Dahlemense* zu bezeichnen.

Von besonderem Interesse für unsere Vorstellungen über die Natur der Virusmutationen scheint mir die Tatsache zu sein, daß auch von diesem Virus eine spontane Mutante isoliert und vermehrt werden konnte, die als „Parallelmutation" zu *flavum* aufgefaßt werden kann. Wir bezeichnen den so entstandenen Stamm als var. *luridum*. Dieser Stamm verhält sich hinsichtlich der Bildung nekrotischer Primärsymptome auf „Java"-Tabak und ihrem Fehlen auf *Phaseolus vulgaris* wie die subspec. *Dahlemense*. In seinen Symptomen auf *Nicotiana tabacum* „Samsun" weicht er in der gleichen Richtung von *Dahlemense* ab wie *flavum* von *vulgare*: 1. Als Primärsymptome entstehen auf „Samsun-Tabak" gelbe Flecken, 2. an Stelle der schwachen Hellgrün-Dunkelgrün-Fleckung tritt als Sekundärsymptom eine Gelb-Grün-Fleckung auf. 3. Die Wachstumshemmung ist gegenüber *Dahlemense* in etwa gleichem Maße verstärkt wie die von *flavum* gegenüber *vulgare* (Fig. 1g).

Die genetischen Beziehungen der hier beschriebenen verschiedenen Stämme des Tabakmosaikvirus sind in folgendem Schema zusammengefaßt:

Die starken Pfeile bezeichnen die sicher beobachteten Mutationen, die schwachen wahrscheinliche, aber nicht sicher beobachtete Mutationen.

Unter „Parallelmutaionen" bei Organismen versteht man Mutationen des gleichen Gens zum gleichen Allel bei verschiedenen Sippen. Die Proteinmoleküle zweier zwar nahe verwandter, aber doch deutlich verschiedener Viren müssen an bestimmten Stellen Verschiedenheiten ihres chemischen Baues aufweisen, die die spezifische Symptomausbildung der beiden Viren bedingen. Für andere Stellen der Moleküle ist eine übereinstimmende Struktur anzunehmen. Das Vorkommen von „Parallelmutationen" bei solchen Viren deutet darauf hin, daß an diesen Stellen ihrer Moleküle gleichartige oder ähnliche Veränderungen auftreten können.

Es wird eine wichtige Aufgabe der serologischen und chemischen Bearbeitung der Virusproteine von *vulgare*, *flavum*, *Dahlemense* und *luridum* sein, diese geforderten Verschiedenheiten und Übereinstimmungen im Molekülbau aufzufinden.

Berlin-Dahlem, Arbeitsstätte für Virusforschung der Kaiser Wilhelm-Institute für Biochemie und Biologie, den 1. Dezember 1941.

G. Melchers.

Zur vergleichenden Charakterisierung einiger Mutanten des Tabakmosiakvirus.

Bei der großen theoretischen und praktischen Bedeutung der Virusmutationen ist es wichtig, die den Mutationen zugrunde liegenden chemischen Veränderungen näher kennenzulernen. Es wurden daher einige der von G. Melchers (s. vorstehende Mitteilung) biologisch isolierten Mutanten des Tabak-Mosaik-Virus (TM.-Virus) von uns vergleichend untersucht. Die Ergebnisse sollen später ausführlich veröffentlicht werden. An dieser Stelle berichten wir zunächst über die *elektrophoretische Charakterisierung* des *flavum*- und *tenue*-Stammes und ihren Vergleich mit dem normalen TM.-Virus. Diese Stämme sind *chemisch* dem TM.-Virus sehr ähnlich. Die *elektronenmikroskopischen* Abbildungen zeigen, daß es sich wie beim TM.-Virus um stäbchenförmige Moleküle handelt, sie *kristallisieren* wie das TM.-Virus in parakristallinen Nadeln und stehen sich auch *serologisch* sehr nahe. Trotz der nahen Verwandtschaft ergaben die Messungen der Wanderungsgeschwindigkeiten im elektrischen Feld in Abhängigkeit vom p_H charakteristische Unterschiede

Zur Spaltung von Virusproteinen der Tabakmosaik-Gruppe.

Läßt man Pyridin oder Natronlauge auf das Protein des normalen Tabakmosaikvirus einwirken, so zerfällt das Riesenmolekül unter Abspaltung von Nucleinsäure in zahlreiche kleinere Bruchstücke. Trotzdem ist das in sehr guter Ausbeute erhältliche nucleinsäurefreie Spaltprotein elektrochemisch einheitlich und scharf charakterisierbar (Pfankuch 1941). Wir stellten nunmehr fest, daß Lösungen dieses Spaltproteins auch weitgehend homodispers sind. Das TM-Virus muß daher aus gleich großen und elektro-chemisch gleichen Bausteinen aufgebaut sein.

Als Sedimentationskonstante (SK.) fanden wir für das Spaltprotein sowohl bei Pyridin- wie bei Natronlaugespaltung bei einem p_H von 7,8 in m/20-Phosphatpuffer $s_{20} = 32$. Da die Spaltung des TM-Virus nachweisbar quer zur Längsachse des Moleküls erfolgt, kann man mit angenähert kugelförmigen Molekülen und normalen Reibungskoeffizienten rechnen. Mit einem Wert $f/f_0 = 1,20$ und der obigen SK errechnet sich für das Spaltprotein ein Molekulargewicht von 1,3 Millionen. Schreibt man dem Tabakmosaikvirus die Abmessungen 15 · 160 mμ zu, so beträgt sein Molekulargewicht 23 Millionen und das obige Spaltprotein stellt $^{1}/_{16}$ des ganzen Moleküls dar. Es ist nicht anzunehmen, daß dieses Protein bereits die kleinste Untereinheit im Virusmolekül darstellt, da Spaltungen mit Decyl- und Dodecylsulfat sehr viel weiter geführt werden können.

Größere Bruchstücke des TM-Virus lassen sich nachweisen, wenn die Spaltung unter milderen Bedingungen vorgenommen wird, z. B. bei gepufferten p_H-Werten von 11—12. In starker Abhängigkeit von den Versuchsbedingungen (Konzentration, Einwirkungsdauer, Auszentrifugieren der höhermolekularen Anteile und Wiederlösen) lassen sich Proteinkomponenten entweder fast rein oder im Gemisch miteinander nachweisen mit den SKK 156, 125 und 85. Diese Komponenten sprechen wir als $^{3}/_{4}$-, $^{1}/_{2}$- und $^{1}/_{4}$-Moleküle an. Wir bestätigen damit die elektronenmikroskopischen Befunde von Kausche, Pfankuch und Ruska (1941), die eine Längenstatistik beschallter Virusmoleküle aufstellten und in Abhängigkeit von der Beschallungszeit sprunghafte Verschiebungen der häufigsten Längen nach kleineren Werten hin, bis zu 80 mμ = halben Molekülen, feststellten.

Berlin-Dahlem, Dienststelle für Biochemie der Biologischen Reichsanstalt, den 5. Januar 1943.

E. Pfankuch. F. Piekenbrock.

Über die Spaltung des Tabakmosaikvirus in niedermolekulare Proteine und die Rückbildung hochmolekularen Proteins aus den Spaltstücken.

Das Tabakmosaikvirus ist ein Nucleoproteid mit einem Molekulargewicht von etwa 23000000[1]. Wie physikalisch-chemische und elektronenmikroskopische Untersuchungen gezeigt haben, besitzt es eine charakteristische stäbchenförmige Gestalt mit einem Durchmesser von 15 mμ und einer Länge von etwa 200 mμ. Das TM.-Virus ist ein relativ stabiles Protein, das in einem p_H-Bereich von 2,5—9 lange Zeit unverändert bleibt. Um auf chemischem Wege Einblick in die Struktur dieses Riesenmoleküls zu erhalten, erscheint es notwendig, dieses unter möglichst milden Bedingungen in kleinere einfachere Bausteine zu zerlegen. Bei unseren elektrophoretischen Untersuchungen beobachteten wir nun oberhalb p_H 9 einen Zerfall des Virus in mehrere elektrochemisch verschiedene Komponenten. Diese knapp außerhalb der p_H-Stabilitätsgrenze auftretenden Spaltprodukte wurden näher untersucht. Durch präparative Anwendung des Elektrophoreseapparates von Tiselius und der luftgetriebenen Ultrazentrifuge gelang es, 3 verschiedene einheitliche Eiweißstoffe zu isolieren. Diese erwiesen sich als 1. unverändertes Ausgangsmaterial, 2. ein niedermolekulares Nucleoproteid und 3. ein niedermolekulares, nucleinsäurefreies Protein.

Infolge ihres Nucleinsäuregehaltes besitzen die beiden erstgenannten Proteine eine hohe negative Ladung, wandern im alkalischen Gebiet schnell zur Anode und können auf diese Weise von der dritten, nucleinsäurefreien Komponente abgetrennt werden. Die Trennung des niedermolekularen Nucleoproteids von dem hochmolekularen Ausgangsmaterial erfolgte durch Zentrifugierung bei 25000 Touren-Minute, wobei das unveränderte TM.-Virus quantitativ ausgeschleudert wird. Bei einem unserer Versuche wurden aus 400 mg TM.-Virus nach 72stündigem Stehen bei 0° in $^{m}/_{100}$ Glykokoll/NaOH-Puffer von p_H 9,6 isoliert: 64 mg unverändertes TM.-Virus, 55 mg niedermolekulares Nucleoproteid und 100 mg nucleinsäurefreies Protein. Jede Fraktion wurde nochmals gereinigt und für sich untersucht.

Das nucleinsäurefreie Protein enthielt keine Phosphorsäure mehr und zeigte im Ultraviolett das Absorptionsspektrum eines reinen nucleinsäurefreien Eiweißstoffes. Die Untersuchung in der Ultrazentrifuge, elektrophoretische und Diffusionsmessungen zeigten, daß es sich um einen einheitlichen Eiweißstoff handelt. Die Beobachtung der Sedimentation in der Ultrazentrifuge erfolgte sowohl mit der Schlieren- als auch mit der Skalenmethode. In m/10-Phosphatlösung ergab sich die Sedimentationskonstante als Mittel von mehreren Versuchen zu $s_{20} = 8,7 \cdot 10^{-13}$ cm sec^{-1} dyn^{-1} (Fig. 1). Die Diffusionskonstante in der gleichen Salzlösung wurde gemeinsam mit G. Bergold nach der Lammschen Methode zu $D_{20} = 2,2 \cdot 10^{-7}$ cm^2/sec bestimmt. Aus s_{20} und D_{20} berechnet sich für das Protein ein Molekulargewicht von 360000 (= $^{1}/_{70}$ des Molekulargewichtes von TM.-Virus). Auch in seinen elektrochemischen Eigenschaften ist das Protein einheitlich. Bei p_H 9 ist die anodische Beweglichkeit um 60% geringer als die des TM.-Virus.

In dieser Eigenschaft unterscheidet es sich von dem 2. Spaltprodukt, das bei diesem p_H etwa die gleiche Wanderungsgeschwindigkeit wie das TM.-Virus besitzt. Diese Spaltkomponente muß demnach noch Nucleinsäure enthalten. Es besitzt jedoch die gleiche Sedimentationskonstante und demnach wohl etwa das gleiche Molekulargewicht wie das nucleinsäurefreie Spaltprotein.

Beide Spaltkomponenten sind biologisch inaktiv. Ihrer Größe nach stimmen sie mit der röntgenographisch festgestellten Elementarzelle des TM.-Virus überein, die eine Dimension von 68 · 87 Å und ein Molekulargewicht von 370000 besitzen soll[2]; sie sind sicher verschieden von den Spaltprodukten, die von E. Pfankuch[3] durch Einwirkung von 5proz. NaOH aus dem TM.-Virus erhalten wurden. Die Eigenschaften der isolierten Komponenten sind in folgender Tabelle zusammengestellt:

Bei der näheren Untersuchung der Spaltprodukte ergab sich eine bemerkenswerte Beobachtung. Wurde die neutrale oder schwach alkalische Lösung der nucleinsäurefreien niedermolekularen Spaltkomponente auf ein p_H von etwa 5 gebracht und daraufhin in der Ultrazentrifuge untersucht, so war von dem niedermolekularen Protein nichts mehr

Bezeichnung	1. TM-Virus	2. Nucleinsäurehaltiges Spaltprodukt	3. Nucleinsäurefreies Spaltprodukt

2.1.3 Cancer

German-speaking scientists dominated the early field of cancer research and cancer prevention (Figs. 2.25–2.32).[6] This field is far larger, and had far more German-speaking creators and discoveries, than can be properly covered in this brief section. Historian of science Robert Proctor gave an overview of some of the remarkably early and remarkably numerous cancer-related discoveries in the German-speaking world [Proctor 1999, pp. 17–19, 281–283]:

> German cancer research—and medical research more generally—was the most advanced in the world by the time of the *Machtergreifung* (1933). German scientists were the first to discover skin cancers caused by coal tar distillates, and the first to show that uranium mining could cause lung cancer (both in the 1870s). Germans were the first to identify a bladder cancer hazard of aniline dye manufacture (in 1895),[14] a lung cancer hazard from chromate manufacture (1911),[15] and a skin cancer hazard of sunlight exposure (1894).[16] German physicians were the first to diagnose an X-ray-induced cancer (in 1902) and the first to prove, by animal experimentation, that X-rays could cause leukemia (1906). They were even the first to suggest that domestic indoor radon might prove to be a health hazard, in 1907.[17]
>
> There are many other examples one can name[18]—and in the interest of completeness (and at the risk of tedium), I shall continue. Johannes Müller in the 1830s pioneered the microscopic analysis of malignancies, identifying tumors as composed of cells, and Rudolf Virchow in Berlin in the 1860s developed the theory of cancer as caused by local "irritations."[19] Germans were pioneers of cancer transplant research,[20] and early in the development of the theory of dose-response latency (*Latenzzeit*).[21] Germans were among the first to propose a major role for hormones in carcinogenesis[22] and were early on aware of what is sometimes today called the "xenoestrogen hypothesis"—the idea that powerful petrochemical carcinogens such as methylcholanthrene may work by mimicking the body's natural hormones.[23] It was a Munich pathologist (Max Borst) who first classified tumors according to their histogenesis, the method used today by the World Health Organization to classify cancers.[24]
>
> The list goes on: Germans were the first to utilize tissue stains as chemotherapeutic agents (in 1922),[25] and were the first to inject thorotrast (thorium dioxide) into patients to improve the contrast in X-ray photographic plates (1928).[26] German geneticists were the first to show that colon cancer could be inherited as a dominant trait, and it was a German zoologist—Theodor H. Boveri—who first proposed that chromosomal abnormalities might be responsible for the onset of malignancies (1902).[27] Germany was the site of the first international congress of cancer research (Heidelberg and Frankfurt, in 1906)[28] and the first country to establish a permanent journal devoted exclusively to cancer research.[29] Germany pioneered the optical diagnosis of cancer, being home to the development of not just X-rays and the colposcope but also the rectal endoscope—a candlelit version of which was introduced in Frankfurt in 1807.[30] German was arguably, at least for a time, the *language* of international cancer research[...] Germans were also

> apparently the first to suggest that secondhand tobacco smoke might be a cause of lung cancer—in 1928.[32]
>
> German scientists in the mid-1930s elaborated on this scientific base. The Reich Anticancer Committee (Reichsausschuss für Krebsbekämpfung) established in 1931 was enlarged, and an ambitious new journal, the *Monatsschrift für Krebsbekämpfung* (Monthly journal for the struggle against cancer), published by the notoriously antisemitic J. F. Lehmann publishing house, was launched in 1933 to coordinate the anticancer effort. More than a thousand medical doctoral theses explored cancer in one form or another in the twelve years of Nazi rule; only diseases of the blood attracted more attention. Cancer registries were established, including the first German registries to record cancer morbidity (incidence) and not just mortality (deaths). Efforts were made to strengthen prevention-oriented public health measures, including occupational safeguards, laws against the adulteration of food and drugs, bans on smoking, and programs to reduce the use of cancer-causing cosmetics, to name only a few.[7]

---

[7] Proctor's endnotes referred to the following cancer researchers:

14. Ludwig Rehn (German, 1849–1930).

15. E. Pfeil (German?, 18??–19??).

16. Paul Gerson Unna (German, 1850–1929).

17. Albert Frieben (German?, 18??–19??), Kurt Ziegler (German?, 18??–19??), Heinrich W. Schmidt (German?, 18??–19??), Ekkehard Schmid (German?, 18??–19??), and Nikolaus von Jagić (German/Austrian, 1875–1956).

18. Richard von Volkmann (German, 1830–1889) and Martha Schmidtmann (German 1892–1981).

19. Johannes Peter Müller (German states, 1801–1858) and Rudolf Virchow (German, 1821–1902).

20. Arthur Hanau (Swiss, 18??–19??).

21. Kurt Rostoski (German?, 18??–19??), Erich Saupe (German?, 1893–19??), and Christian Georg Schmorl (German, 1861–1932); Otto Teutschlaender (German?, 18??–19??).

22. Jens Paulsen (German, 18??–19??).

23. Karl Heinrich Bauer (German, 1890–1978) and Adolf Butenandt (German, 1903–1995).

24. Max Borst (German, 1869–1946).

25. Rudolf Roosen (German?, 18??–19??).

26. Theodor Blühbaum (German?, 18??–19??), Karl Frik (German, 1878–1944), and Helmut Kalkbrenner (German?, 18??–19??).

27. Otto Jüngling (German, 1884–1944) and Theodor Boveri (German, 1862–1915). As shown in Fig. 2.25, Boveri conducted extensive studies of cell division (mitosis), chromosome structure, and chromosome abnormalities. In 1902 he realized that cancer can be caused by pro-mitotic (cell-division-inducing) mutations from radiation, chemicals, or viruses.

28. George Meyer (German?, 18??–19??).

29. *Zeitschrift für Krebsforschung.*

Several other prominent German-speaking cancer researchers should also be mentioned here.

Johannes Fibiger (Danish but studied under Robert Koch and Emil von Behring, lived 1867–1928) conducted important clinical trials on diagnostics and therapeutics for diptheria. He won the Nobel Prize in Physiology or Medicine in 1926 for experiments showing that infectious pathogenic organisms can induce cancer. Although his specific conclusions regarding those pathogens (he focused on helminths) were later found to be incorrect, his experiments spurred a great deal of cancer research by other scientists, and his general conclusions have ultimately proven correct, especially with regard to the role of viruses in causing certain types of cancer. Professor W. Wernstedt, Dean of the Royal Caroline Institute, described Fibiger's research [https://www.nobelprize.org/prizes/medicine/1926/ceremony-speech/]:

> *But Fibiger's discovery had a still greater significance.* The possibility of experimentally producing cancer gave to the particular research into this illness an invaluable and badly needed method, lacking until this time, allowing the elucidation of some of the obscure points in the problem of cancer. Fibiger's discovery also gave remarkable impetus to research. Whereas research had, in many respects, entered upon a period of stagnation, Fibiger's discovery marked the beginning of a new era, of a new epoch in the history of cancer, to which the fruitful research made by him gave fresh vigour. From his discoveries we have continued to march forward and have gained valuable ideas as to the nature of this illness.

Arnold Graffi (Austrian/German, 1910–2006) discovered some of the mechanisms by which chemicals and viruses can cause cancer, and helped to develop chemotherapeutic methods to target cancer cells for destruction.

Paul Grawitz (German, 1850–1932) studied various types of cancers, and renal cell carcinoma is named Grawitz's tumor after him.

Rudolf Krönlein (Swiss, 1847–1910) pioneered many types of surgical operations, including surgeries to remove certain kinds of tumors.

Fritz Lickint (German, 1898–1960) began medical studies of smokers vs. nonsmokers in the 1920s, published evidence that smoking causes cancer in 1929, and published a >1200 page medical book on the detailed pathology caused by smoking in 1939. His discoveries led to public health campaigns against smoking, first in Germany and much later worldwide [Haustein 2004]. See Fig. 2.26.

Hans Sachs (German, 1877–1945) studied interactions between the immune system and cancer.

Otto Heinrich Warburg (German, 1883–1970) discovered important metabolic changes that distinguish cancer cells from normal cells.

Creators from the German-speaking world also developed sunscreen lotion, which reduces the incidence of skin cancer.[8]

---

30. Leopold Schönbauer (Austrian, 1888–1963) and Erna Schmidt-Überreiter (German?, 18??–19??).

32. Ernst Schönherr (German?, 18??–19??).

[8] Eder and Freund 1922; Hammer 1891; Hausser and Vahle 1922; Urbach 2001; Vogt 2008; von Weiher 1983;

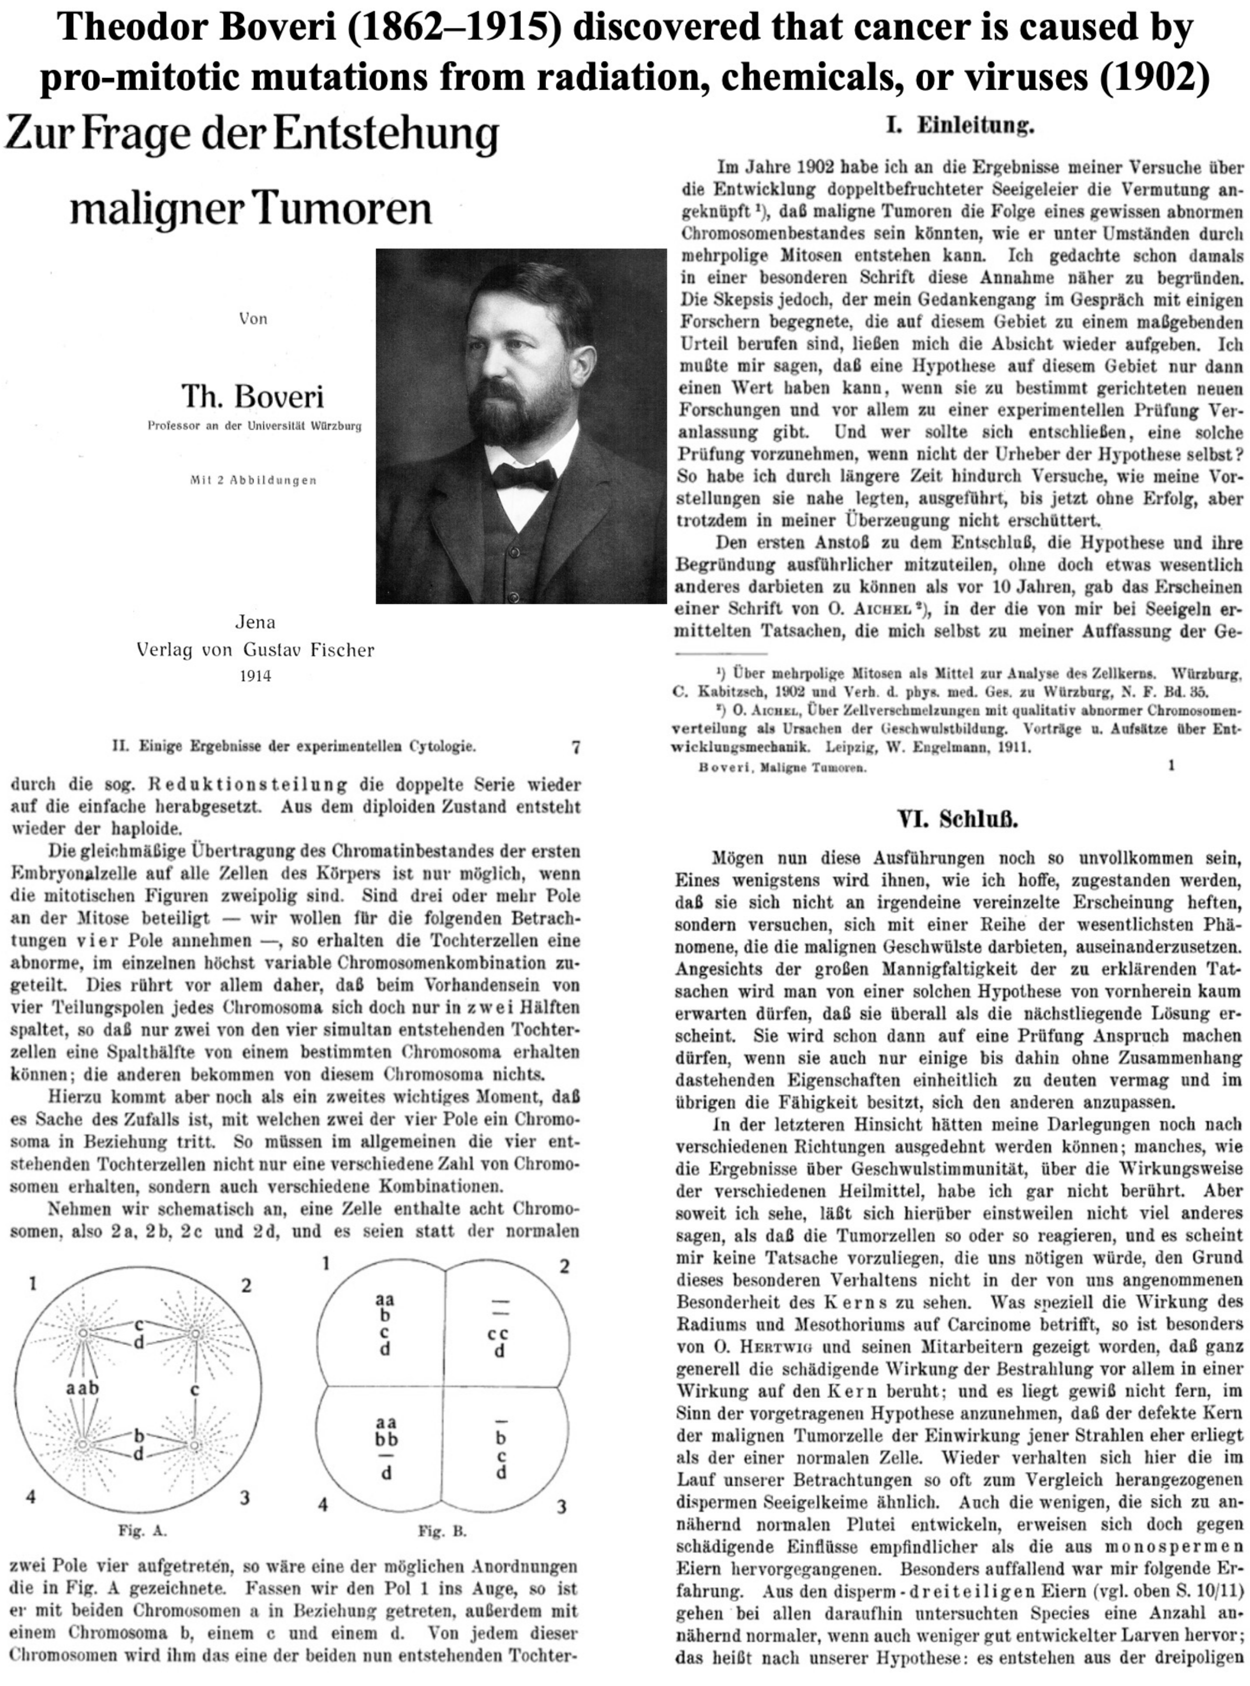
During the period 1889–1891, Erik Johan Widmark (Swedish but closely coupled to the German-speaking research world, 1850–1909) and Friedrich Hammer (German, 1860–1943) demonstrated via a series of experiments that ultraviolet light causes sunburns and suntans, and that those effects could be reduced by coating the skin with a protective layer of certain natural plant extracts. See Fig. 2.33.

In 1922, Josef Maria Eder (Austrian, 1855–1944) and Leopold Freund (Austrian, 1868–1943) invented the first chemical sunscreen, which was marketed as Antilux. See Fig. 2.34. Freund also invented and successfully demonstrated radiation therapy in 1896 (p. 1509).

In 1938, Franz Greiter (Austrian, 1919–1985) developed an improved sunscreen that was ultimately marketed as Piz Buin Gletscher Crème, as shown in Fig. 2.35.

During the period 1922–1956, Karl Wilhelm Hausser (German, 1887–1933), his wife Isolde (Ganswindt) Hausser (German, 1889–1951), Wilhelm Vahle (German?, 18??–19??), Friedrich Ellinger (German, 1900–1962), and Rudolf Schulze (German, 1906–1974) developed increasingly sophisticated methods of measuring the sun protection factor (SPF) offered by sunscreens, as well as the cellular damage caused by ultraviolet exposure. See Fig. 2.35. Isolde Hausser was the daughter of Hermann Ganswindt (pp. 1643, 1801, and 1953), ran a department at the Kaiser Wilhelm Institute for Medical Research, and also made important contributions to radiation therapy for cancer.

Widmark 1889.



Theodor Boveri (1862–1915) discovered that cancer is caused by pro-mitotic mutations from radiation, chemicals, or viruses (1902)

II. Einige Ergebnisse der experimentellen Cytologie. 7

durch die sog. Reduktionsteilung die doppelte Serie wieder auf die einfache herabgesetzt. Aus dem diploiden Zustand entsteht wieder der haploide.

Die gleichmäßige Übertragung des Chromatinbestandes der ersten Embryonalzelle auf alle Zellen des Körpers ist nur möglich, wenn die mitotischen Figuren zweipolig sind. Sind drei oder mehr Pole an der Mitose beteiligt — wir wollen für die folgenden Betrachtungen vier Pole annehmen —, so erhalten die Tochterzellen eine abnorme, im einzelnen höchst variable Chromosomenkombination zugeteilt. Dies rührt vor allem daher, daß beim Vorhandensein von vier Teilungspolen jedes Chromosoma sich doch nur in zwei Hälften spaltet, so daß nur zwei von den vier simultan entstehenden Tochterzellen eine Spalthälfte von einem bestimmten Chromosoma erhalten können; die anderen bekommen von diesem Chromosoma nichts.

Hierzu kommt aber noch als ein zweites wichtiges Moment, daß es Sache des Zufalls ist, mit welchen zwei der vier Pole ein Chromosoma in Beziehung tritt. So müssen im allgemeinen die vier entstehenden Tochterzellen nicht nur eine verschiedene Zahl von Chromosomen erhalten, sondern auch verschiedene Kombinationen.

Nehmen wir schematisch an, eine Zelle enthalte acht Chromosomen, also 2 a, 2 b, 2 c und 2 d, und es seien statt der normalen zwei Pole vier aufgetreten, so wäre eine der möglichen Anordnungen die in Fig. A gezeichnete. Fassen wir den Pol 1 ins Auge, so ist er mit beiden Chromosomen a in Beziehung getreten, außerdem mit einem Chromosoma b, einem c und einem d. Von jedem dieser Chromosomen wird ihm das eine der beiden nun entstehenden Tochter-

Fig. B.

I. Einleitung.

Im Jahre 1902 habe ich an die Ergebnisse meiner Versuche über die Entwicklung doppeltbefruchteter Seeigeleier die Vermutung angeknüpft [1]), daß maligne Tumoren die Folge eines gewissen abnormen Chromosomenbestandes sein könnten, wie er unter Umständen durch mehrpolige Mitosen entstehen kann. Ich gedachte schon damals in einer besonderen Schrift diese Annahme näher zu begründen. Die Skepsis jedoch, der mein Gedankengang im Gespräch mit einigen Forschern begegnete, die auf diesem Gebiet zu einem maßgebenden Urteil berufen sind, ließen mich die Absicht wieder aufgeben. Ich mußte mir sagen, daß eine Hypothese auf diesem Gebiet nur dann einen Wert haben kann, wenn sie zu bestimmt gerichteten neuen Forschungen und vor allem zu einer experimentellen Prüfung Veranlassung gibt. Und wer sollte sich entschließen, eine solche Prüfung vorzunehmen, wenn nicht der Urheber der Hypothese selbst? So habe ich durch längere Zeit hindurch Versuche, wie meine Vorstellungen sie nahe legten, ausgeführt, bis jetzt ohne Erfolg, aber trotzdem in meiner Überzeugung nicht erschüttert.

Den ersten Anstoß zu dem Entschluß, die Hypothese und ihre Begründung ausführlicher mitzuteilen, ohne doch etwas wesentlich anderes darbieten zu können als vor 10 Jahren, gab das Erscheinen einer Schrift von O. AICHEL [2]), in der die von mir bei Seeigeln ermittelten Tatsachen, die mich selbst zu meiner Auffassung der Ge-

VI. Schluß.

Mögen nun diese Ausführungen noch so unvollkommen sein, Eines wenigstens wird ihnen, wie ich hoffe, zugestanden werden, daß sie sich nicht an irgendeine vereinzelte Erscheinung heften, sondern versuchen, sich mit einer Reihe der wesentlichsten Phänomene, die die malignen Geschwülste darbieten, auseinanderzusetzen. Angesichts der großen Mannigfaltigkeit der zu erklärenden Tatsachen wird man von einer solchen Hypothese von vornherein kaum erwarten dürfen, daß sie überall als die nächstliegende Lösung erscheint. Sie wird schon dann auf eine Prüfung Anspruch machen dürfen, wenn sie auch nur einige bis dahin ohne Zusammenhang dastehenden Eigenschaften einheitlich zu deuten vermag und im übrigen die Fähigkeit besitzt, sich den anderen anzupassen.

In der letzteren Hinsicht hätten meine Darlegungen noch nach verschiedenen Richtungen ausgedehnt werden können; manches, wie die Ergebnisse über Geschwulstimmunität, über die Wirkungsweise der verschiedenen Heilmittel, habe ich gar nicht berührt. Aber soweit ich sehe, läßt sich hierüber einstweilen nicht viel anderes sagen, als daß die Tumorzellen so oder so reagieren, und es scheint mir keine Tatsache vorzuliegen, die uns nötigen würde, den Grund dieses besonderen Verhaltens nicht in der von uns angenommenen Besonderheit des Kerns zu sehen. Was speziell die Wirkung des Radiums und Mesothoriums auf Carcinome betrifft, so ist besonders von O. HERTWIG und seinen Mitarbeitern gezeigt worden, daß ganz generell die schädigende Wirkung der Bestrahlung vor allem in einer Wirkung auf den Kern beruht; und es liegt gewiß nicht fern, im Sinn der vorgetragenen Hypothese anzunehmen, daß der defekte Kern der malignen Tumorzelle der Einwirkung jener Strahlen eher erliegt als der einer normalen Zelle. Wieder verhalten sich hier die im Lauf unserer Betrachtungen so oft zum Vergleich herangezogenen dispermen Seeigelkeime ähnlich. Auch die wenigen, die sich zu annähernd normalen Plutei entwickeln, erweisen sich doch gegen schädigende Einflüsse empfindlicher als die aus monospermen Eiern hervorgegangenen. Besonders auffallend war mir folgende Erfahrung. Aus den disperm-dreiteiligen Eiern (vgl. oben S. 10/11) gehen bei allen daraufhin untersuchten Species eine Anzahl annähernd normaler, wenn auch weniger gut entwickelter Larven hervor; das heißt nach unserer Hypothese: es entstehen aus der dreipoligen

Ueber den Einfluss des Lichtes auf die vorderen Medien des Auges.[1]

Von

Dr. E. J. Widmark,
Docent der Ophthalmiatrik zu Stockholm.

(Aus dem physiologischen Laboratorium des Carolinischen medico-chirurgischen Instituts in Stockholm.)

Einleitung.

Von Alters her weiss man, dass die Einwirkung starken Lichtes auf das Auge zu einer dauernden Schädigung des Sehvermögens, ja sogar zu vollständiger Blindheit führen kann. Solche Angaben betreffs des Sonnenlichtes oder des Blitzes finden wir schon in der älteren Litteratur. Galenus[2] erwähnt solcher Fälle, und von Galilei sagt man, dass er bei der Beobachtung der Sonnenflecken blind geworden sei.[3]

Durch die Erfindung des Augenspiegels erhielt man ein Mittel, die im Auge bei einer derartigen Einwirkung des Lichtes entstandenen Veränderungen genau zu studiren. Schon 1854 beschrieb E. Jäger zwölf Fälle von Blendung durch Sonnenlicht, von denen sechs materielle Veränderungen, und vier von diesen eine Chorioiditis mit Exsudat[4] zeigten. Arlt[5] erwähnt eines Patienten, der sich durch die Anschauung einer Sonnenfinsterniss am 28. Juli 1851 ein centrales Skotom zugezogen hatte und bei welchem die einige Zeit nachher mit dem Augenspiegel

During the period 1922–1956, Karl Wilhelm Hausser, his wife Isolde (Ganswindt) Hausser, Wilhelm Vahle, Friedrich Ellinger, and Rudolf Schulze developed increasingly sophisticated methods of measuring the sun protection factor (SPF) offered by sunscreens.

2.1.4 Proteins and Enzymes

Figures 2.36–2.37 show the 20 standard amino acids and how those are joined together to make proteins. Many proteins are enzymes, essentially tiny biological machines that are specialized to do a particular task. As presented in Figs. 2.38–2.46, creators from the German-speaking world made many critical contributions to our knowledge about proteins and enzymes.[9]

Johann Purkinje (Austrian/Czech, 1787–1869, Fig. 2.40) was most famous for his contributions to cell biology and microscopy (p. 78), yet in 1836 he also discovered that pancreatic extracts contained enzymes that digested proteins.

Theodor Schwann (German, 1810–1882, Fig. 2.40), another cell biologist (p. 79), also discovered protein-digesting enzymes in 1836. He identified the enzyme pepsin from the stomach lining and studied its properties. He then went on to investigate the enzymatic processes of fermentation.

Wilhelm Kühne (German, 1837–1900) coined the word "enzyme." He studied the protein-digesting enzyme trypsin from the pancreas (drawing upon the earlier work by Purkinje and Schwann), and he also studied proteins in muscle. See Fig. 2.41.

Franz Hofmeister (Austrian, 1850–1922) established many methods of protein chemistry that are still used today (Fig. 2.42). He discovered the peptide bonds in proteins, the effect of various salts on proteins, differing protein solubilities, methods of protein purification, and methods of protein crystallization [Abernethy 1967].

Hermann Emil Fischer (German, 1852–1919, Fig. 2.38) studied enzymes involved in the synthesis of sugars and purine molecules, and made numerous other contributions to organic chemistry. He won the Nobel Prize in Chemistry in 1902 (p. 469). One of his students, Max Bergmann, built upon Fischer's work on proteins and enzymes by developing methods to analyze and synthesize proteins.

Albrecht Kossel (German, 1853–1927, Fig. 2.43) found that proteins were composed of individual amino acids. He determined the chemical composition of DNA and RNA too [Mary Ellen Jones 1953]. For his discoveries regarding proteins and nucleic acids, he won the Nobel Prize in Physiology or Medicine in 1910 (p. 90). In a 1911 lecture, Kossel demonstrated his remarkably early and detailed knowledge of protein structure [Olby 1994, p. 77]:

> [W]e must remember that the proteins are composed of *Bausteine* [building blocks, i.e. amino acids] united in very different ways[...] The number of *Bausteine* which can take part in the formation of the proteins is about as large as the number of letters in the alphabet. When we consider that through the combination of letters an infinitely large number of thoughts may be expressed, we can understand how vast a number of the properties of the organism may be recorded in the small space which is occupied by the protein molecules. [...] We may also comprehend how great and important the task is to determine the structure of the proteins and why the biochemist has devoted himself with so much industry to their analysis.

Eduard Buchner (German, 1860–1917, Fig. 2.38) discovered cell-free enzymes for fermentation, for which he won the Nobel Prize in Chemistry in 1907. Professor the Count K. A. H. Mörner, President of the Royal Swedish Academy of Sciences, praised the revolutionary nature of Buchner's discoveries [https://www.nobelprize.org/prizes/chemistry/1907/ceremony-speech/]:

> Under these circumstances it can easily be understood that a great sensation was created when E. Buchner, after many years' work, succeeded in showing that alcoholic fermentation could be produced from the juices expressed from yeast cells, free from live cells. He demonstrated incontrovertibly that this fermentation was due to a ferment produced by the yeast cells, from which it can be separated. Fermentation is not a direct expression of life by yeast cells; the cells can be killed and destroyed, while the ferment remains.
>
> By Buchner's work, the fermentation mentioned and various other processes analogous to it have been freed from the shackles which previously held them and which prevented any progress in research. Now, no special difficulty is encountered in obtaining from yeast cells and various other cells an ample amount of powerfully active cell substance which is free from live cells. Numerous clarifying investigations into its properties have also been made, partly by Buchner himself and partly by others. Hitherto inaccessible territories have now been brought into the field of chemical research, and vast new prospects have now been opened up to chemical science.

Friedrich Kutscher (German, 1866–1942, Fig. 2.40) conducted important early research on the molecular structures of amino acids, proteins, and nucleic acids. In his early career, he worked closely with Albrecht Kossel.

Richard Willstätter (German, 1872–1942, Fig. 2.40) is best known for his discoveries regarding the molecular structures of chlorophyll, for which he won the Nobel Prize in Chemistry in 1915 (p. 407). However, he subsequently went on to conduct extensive investigations of the nature and properties of enzymes.

Hans von Euler-Chelpin (German, 1873–1964, Fig. 2.38) made many discoveries regarding enzymes and won the Nobel Prize in Chemistry in 1929. Professor H.G. Söderbaum, Chairman of the Nobel Committee for Chemistry, explained von Euler-Chelpin's work [https://www.nobelprize.org/prizes/chemistry/1929/ceremony-speech/]:

> In the same measure as research in this department has made new conquests, a clearer and clearer insight has been gained into the importance of this discovery. In particular the work of von Euler and his pupils during the last few years greatly contributed to the unravelling of the mechanism of phosphorization.
>
> The primary function of phosphoric acid in fermentation consists, according to von Euler, in the fact that in cooperation with an enzyme it gives rise to glucose monophosphate, identical with the monophosphate discovered by Harden and Robison. This phosphate afterwards undergoes a mutation in the presence of co-zymase, inasmuch as a glucose diphosphate and an active glucose are formed, after which the latter yields the necessary material for the subsequent stages of the fermentation.

> This demonstration of the part of mutase played by the co-zymase, or in other words of the identity of co-zymase and co-mutase, is of fundamental importance, for it has fully revealed the central position in the process of fermentation of the complementary enzyme in question.
>
> The researches of von Euler and his pupils have further led to the concentration of the co-zymase and to a far more exact study of its properties than had been previously possible. They have been able to determine approximately its molecular weight, which has been found to be about 490; and they have also been able to draw certain definite conclusions concerning its chemical nature, which make it highly probable that we have here what the chemists call a pentosenucleoside. The production of a co-zymase with a high activity has also shown in a brilliant manner the character of that enzyme as a specific activator.

As illustrated in Fig. 2.45, Leonor Michaelis (German, 1875–1949) and Maud Menten (Canadian, worked in Germany, 1879–1960) studied the chemical reaction rates of enzymes. Their experimental and theoretical methods of analyzing enzyme-catalyzed reaction rates (Michaelis-Menten kinetics, Michaelis-Menten graphs, the Michaelis-Menten equation, etc.) are still widely used in biology and chemistry.

Otto Röhm (German, 1876–1939), shown in Fig. 2.44, pioneered the industrial use of enzymes for applications such as leather production (1906), washing detergents (1914), pharmaceuticals (1920), and juice processing (1934). In many ways, he could be regarded as the founder of the entire field of industrial biotechnology (see Appendix A for more examples). Röhm also invented transparent polymethylacrylic plastic (plexiglass) in 1928 (p. 654). With the businessman Otto Haas (German, 1872–1960), he founded the company of Röhm and Haas to capitalize on his inventions. Haas moved to Philadelphia to establish a branch of the company there, thereby bringing knowledge of Röhm's biotechnology methods to the United States.

Building upon the earlier work of Eduard Buchner, Carl Neuberg (German, 1877–1956, Fig. 2.40) meticulously worked out many of the key enzymatic steps and mechanisms involved in fermentation and other biochemical pathways.

Max Bergmann (German, 1886–1944) received his Ph.D. under Hermann Emil Fischer in 1911. Bergmann spent his entire career creating methods of determining the amino acid sequences of natural proteins and of artificially synthesizing proteins with specific amino acid sequences (Fig. 2.46). Such methods have been widely used ever since to analyze and synthesize proteins in laboratories. In 1933, Bergmann moved to the United States, where he attracted new students to harness and extend his research. Leonidas Zervas (1902–1980) was Greek but was educated and worked in Germany. He worked closely with Bergmann in Germany and in the U.S. after Bergmann moved there; later he continued his protein research in Greece.

Kurt Felix (German, 1888–1960, Fig. 2.38) conducted important research on proteins at the University of Munich from the 1920s onward.

Felix Haurowitz (Czech, 1896–1987, Fig. 2.39) made a number of protein structural studies and discoveries about antibodies (immunoglobulins) as well as hemoglobin.

In the 1930s and early 1940s, German-speaking scientists developed several egg protein substitutes that consisted of protein extracted and processed on an industrial scale from cultured yeast, animal blood plasma (Plenora), fish (Eiweiss), and milk (Milei) [BIOS 236; BIOS 1417; BIOS 1481; BIOS 1513]. See p. 521.

Klaus H. Hofmann (German/Swiss, 1911–1995, Fig. 2.39) chemically synthesized analogs of amino acids, studied the mechanisms of protein-cleaving trypsin and RNA-cleaving RNaseA enzymes, chemically synthesized peptide hormones, and made other discoveries regarding protein structures and functions. He also did important work on steroid hormones.

Max Perutz (Austrian, 1914–2002, Fig. 2.40) developed and demonstrated methods of determining detailed three-dimensional protein structures [Medawar and Pyke 2000; Perutz 1989, 1998]. He won the 1962 Nobel Prize in Chemistry for working out the structure of the hemoglobin protein (Fig. 2.47).

Edmond Fischer (Swiss, 1920–, Fig. 2.38) made important discoveries regarding protein phosphorylation and dephosphorylation, the methods by which cells regulate the activity of proteins by attaching or removing charged phosphate groups on the proteins. Along with Edwin Krebs, he won the Nobel Prize in Physiology or Medicine in 1992 for that work. Professor Hans Jörnvall of the Nobel Assembly of the Karolinska Institute explained the scientific importance of these discoveries [https://www.nobelprize.org/prizes/medicine/1992/ceremony-speech/]:

> And now phosphorylation: one or several small phosphate groups are coupled to a protein, changing its properties. If the parallel with our human workers is pursued further, one could perhaps compare phosphorylation with ballet shoes. Despite their small size they have dramatic effects on their wearer! The shape of the foot is altered and after that, work is like a dance. Edmond Fischer and Edwin Krebs, this year's Laureates, described this principle in the fifties. They showed how muscles liberate an energy-rich form of sugar from its storage form by phosphorylation of a protein. After that, science gradually gained insight into the fact that this constitutes a general principle manifested in all cellular activities. Today, a considerable part of world bioscience involves protein phosphorylation.
>
> Why this regulation via coupling of small groups? One advantage is that the process is reversible, i.e. the shoes can be taken off and put on, a process which can be repeated again and again. Thus, proteins can be regulated in both directions. Another is that the reactions can be carried out in successive steps, creating a cascade that amplifies the end effect. Much like the hydraulic amplification in a brake: a gentle touch of the pedal can stop even a heavy car. In the world of proteins, Krebs and his collaborators paved the way for this knowledge by studying also the preceding protein in the chain of phosphorylations, while Fischer concentrated his efforts along other lines and, as recently as some years ago, reported the purification of a special type of phosphate-removing protein.
>
> Yet another advantage is that the regulation can be affected by different signals. The system that Fischer and Krebs first studied can be activated either by means of a stress hormone released when we become frightened and our muscles prepare us for escape, or by an act of will when we wish to run for other reasons. Phosphate groups are in these

> two cases attached in response to separate signals, much as they are in all other cellular response systems. What relevance does this have to medicine? The easiest answer is that we all know of the consequences in society from imbalances in economic chain reactions! We are now in a position to start perceiving how illnesses, including common diseases like hypertension and tumors, are accompanied by imbalances in phosphorylations.

Werner Adolf Immerwahr (German, 1924–2006, Fig. 2.39) left Germany during World War II, changed his name to Vernon Ingram, and ultimately became a well-known biology professor at MIT. With support from Max Perutz and other members of the German-speaking scientific diaspora, he spent most of his career studying the roles of proteins in diseases. In the 1950s, Immerwahr/Ingram showed that a mutation changing a single amino acid in hemoglobin was responsible for causing sickle-cell anemia, a hereditary blood disease. Later he studied some of the key proteins involved in neurodegenerative illnesses such as Alzheimer's disease.

Günter Blobel (German, 1936–2018, Fig. 2.38) discovered that many proteins contain a "postal address code" that tells cells where to send the protein so it can do its job. For that discovery, he won the Nobel Prize in Physiology or Medicine in 1999. The Royal Swedish Academy of Sciences summarized his work [https://www.nobelprize.org/prizes/medicine/1999/blobel/facts/]:

> Proteins, molecules composed of chains of amino acids, play a crucial role in life processes in our cells. Proteins are continuously being transported through membranes or walls that both separate the cell from its surroundings and separate the inner parts of the cell, the organelles. In 1975 Günter Blobel showed that in certain cases amino acids in a protein serve as an address label that determines where a protein is to be delivered. Amino acid sequences determine whether a protein is to be passed through the membrane out of the cell or into an organelle or is to be built in the membrane.

For closely related work, see Section 2.1.5 for enzymes involved in metabolism, Section 2.4.1 for hemoglobin protein in red blood cells, and Appendix A for industrial biotechnology methods and applications.

190 W. Kühne:

Ueber das Verhalten verschiedener organisirter und sog. ungeformter Fermente.

Sitzung am 4. Februar 1876.

Hr. W. Kühne berichtet über das Verhalten verschiedener organisirter und sog. ungeformter Fermente. Um Missverständnissen vorzubeugen und lästige Umschreibungen zu vermeiden schlägt Vortragender vor, die ungeformten oder nicht organisirten Fermente, deren Wirkung ohne Anwesenheit von Organismen und ausserhalb derselben erfolgen kann, als *Enzyme* zu bezeichnen. — Genauer untersucht wurde besonders das Eiweiss verdauende Enzym des Pankreas, für welches, da es zugleich Spaltung der Albuminkörper veranlasst, der Name *Trypsin* gewählt wurde. Das Trypsin vom Vortr. zuerst dargestellt und zwar frei von durch dasselbe noch verdaulichen und zersetzbaren Eiweissstoffen, verdaut nur in alkalischer, neutraler, oder sehr schwach sauer reagirender Lösung. Dasselbe wird durch nicht zu kleine Mengen Salicylsäure, welche das Enzym in bedeutenden Quantitäten löst, bei 40° C. gefällt, ohne dabei seine specifische Wirksamkeit zu verlieren. Wird die Fällung in Sodalösung von 1 pCt. gelöst, so verdaut sie höchst energisch unter Bildung von Pepton, Leucin, Tyrosin u. s. w. Nur übermässiger Zusatz von Salicylsäure bis zur Bildung eines dicken Krystallbreies vernichtet die enzymotischen Eigenschaften. Dies Verhalten war kaum zu erwarten, seit Kolbe und J. v. Meyer die hemmende, selbst vernichtende Wirkung kleiner Mengen Salicylsäure auf einige Enzyme hervorgehoben hatten. Die Beobachtungen des Vortr., der ausser dem Trypsin noch das Pepsin eingehender untersuchte, stehen jedoch mit den Angaben von J. v. Meyer, nach welchen Salicylsäure bei einem Gehalte der

Ueber das Trypsin (Enzym des Pankreas),

von W. Kühne.

Cl. Bernard hat sehr richtig angegeben, dass Alkohol aus Pankreassaft eine eiweissartige Substanz ausfälle, die sich in Wasser leicht wieder löse und Corvisart zeigte, dass der aus dem Drüseninfuse so gefällte Körper das von ihm entdeckte Verdauungsvermögen für Albuminstoffe besitze. Es war mir zwar lange bekannt, dass die Alkoholfällung nicht nur peptonisirend, sondern auch zersetzend, Leucin- und Tyrosin-bildend auf Eiweiss wirke; für die Gewinnung des im Pankreas zu vermuthenden Enzyms, etwa wie des Pepsins in der Magenschleimhaut, war aber damit keine weitere Erkenntniss erreicht, denn sehr einfache Versuche ergaben sofort, dass die fragliche Materie sich anscheinend selbst zersetze unter Bildung der bekannten pankreatischen Verdauungsproducte. Nicht anders verhält sich die nach v. Wittich's Verfahren aus dem Glycerinauszuge mit Alkohol gefällte Substanz, ebenso das nach Alkoholbehandlung der Drüsen in Glycerin wiederholt gelöste und mehrfach mit Alkohol gefällte Produkt, welches Hüfner analysirte.

Aus Heidenhain's subtilen Untersuchungen ist die wichtige Thatsache bekannt, dass das Pankreas in seinen Zellen kein fertiges Enzym, sondern ein Zymogen enthält. Nach meinen Erfahrungen wird lebensfrisches Pankreas sogleich wirksam, wenn man es noch warm mit Glaspulver und absolutem Alkohol zerreibt. Ein bei 0^0 aus der so behandelten Drüse bereitetes Wasserextrakt wirkt sofort verdauend, ebenso eine mit 1-procentiger Sodalösung gewonnene Lösung. Lebenswarmes Pankreas mit Glaspulver und Schnee zerrieben, giebt gleich

W. Kühne: Ueber das Sekret des Pankreas. 233

Ueber das Sekret des Pankreas.

Von W. Kühne.

Das Sekret aus temporären Pankreasfisteln von Hunden ist nie frei von geformten Bestandtheilen. Bei Abwesenheit rother Körperchen findet man darin stets farblose Blutkörperchen der kleineren Art, mit träger aber deutlicher amöboïder Bewegung, ausserdem sog. Speichelkörperchen, grösser als jene, kleiner als die des gemischten menschlichen Speichels, von welchen Letzteren sie im Uebrigen in keinem Punkte abweichen. Man beobachtet in den Bauchspeichelkörperchen höchst lebhafte Bewegungen kleiner Körnchen, einen bis vier Kerne, einen glatten Contour und das bekannte Zerplatzen mit nachfolgender Gerinnung. Bei günstiger Temperatur zerfliessen die morphotischen Elemente, indem sie verdaut werden. Farblose Blutkörperchen in sog. Speichelkörperchen umzugestalten gelingt weder mit Pankreassaft noch mit Speichel.

Der Pankreassaft wird nicht nur in der Kälte zähflüssiger, wie es aus Cl. Bernard's Beschreibungen bekannt ist, sondern er zeigt wahre Gerinnung, mit Abscheidung einer Gallerte und eines dünnflüssigeren Theiles, was zuweilen auch bei mittleren Temperaturen beobachtet wird. In silbernen Canülen bildet der Saft häufig derbere, opake Gerinnsel. Solcher Saft mischt sich nicht mit destillirtem Wasser, sondern fällt darin in Gestalt sich trübender und von Membranen überzogener Tropfen zu Boden. Unter Ausschluss der Verdauung, bei 0°, wird so eine gallertig flockige Fällung erhalten, welche in NaCl und

Von W. Kühne.

Gereinigtes Trypsin, welches weder bei der Dialyse, noch an absolutes Glycerin Peptone abgibt und daher in Letzterem unlöslich ist, zerfällt bei einmaligem Aufkochen mit Wasser in etwa $20^0/_0$ coagulirtes Eiweiss und $80^0/_0$ Antipepton; Ersteres ist in Spuren neuen Trypsins verdaulich, wobei Antipepton, Leucin, Tyrosin etc. entstehen, während Letzteres auch mit grossen Mengen Trypsin behandelt keiner Zersetzung mehr unterliegt.

Das Antipepton hat dieselbe Zusammensetzung, wie das Pepsin-Pepton, dieses die der in Verdauung gegebenen, reinen Eiweissstoffe. Längeres Sieden des Antipeptons mit 2 Th. Schwefelsäure und 3 Th. Wasser gibt die bekannten Zersetzungsproducte aller Eiweisskörper, vornehmlich Leucin und Tyrosin. Mit Aetzkali geschmolzen entwickelt das Antipepton Indol.

Bei der Verdauung der Albumine durch Trypsin sind zwei Stadien zu unterscheiden: im ersten wird das Albumin in Peptone umgewandelt, im zweiten eine Hälfte der Peptone (Hemipepton) weiter zersetzt, während die andere als Antipepton übrig bleibt. Die Verdauung der Albumine in Pepsin und Säuren ist von dem ersten Stadium der Trypsinverdauung nicht verschieden, und wenn es auch noch nicht gelingt, aus den Pepsin-Peptonen zwei Körper zu isoliren, so ist es doch sehr wahrscheinlich, dass sie Gemische von Antipepton und einem Hemipepton

Ueber den Bau des Eiweissmoleküls.

Von Prof. Dr. **F. Hofmeister** in Strassburg.

Nach einleitenden Bemerkungen über die Schwierigkeiten, die sich dem Abbau des Eiweissmoleküls entgegenstellen, einem Rückblick auf die diesbezüglichen Arbeiten Lavoisier's, Liebig's, Wöhler's und Pasteur's und einem Hinweise auf die bahnbrechenden Arbeiten E. Fischer's erörtert der Vortragende die wichtigen Ergebnisse, die von einem durchgreifenden Abbau für die Erkenntniss der Konstitution des Eiweissmoleküls zu erwarten sind. Nur durch einen Abbau, der uns die Spaltungsprodukte des Eiweisses in der in seinem Molekül vorhandenen Form bietet, ist eine Förderung dieser Erkenntnisse zu erwarten. Die theils durch Fermentspaltung, theils durch Hydrolyse bis jetzt erhaltenen Körper sind folgende:

I. Körper der aliphatischen Reihe:

Guanidinrest ($CNH(NH_2)$):

Einbasische Monaminsäuren: Glykokoll ($C_2H_5 . NO_2$), Alanin ($C_8H_7NO_2$), Aminobuttersäure ($C_4H_9NO_2$), Aminovaleriansäure ($C_5H_{11}NO_2$), Leucin ($C_6H_{13}NO_2$).

Zweibasische Monaminsäuren: Asparaginsäure ($C_4H_7NO_4$), Glutaminsäure ($C_5H_9NO_4$).

Diaminsäuren: Ornithin ($C_5H_{12}N_2O_2$), Lysin ($C_6H_{14}N_2O_2$), Hystidin ($C_6H_9N_3O_2$).

Thioaminsäuren: Cysteïn ($C_3H_7NSO_2$).

Stickstoffhaltige Kohlenhydrate: Chitosamin ($C_6H_{13}NO_5$).

II. Körper der aromatischen Reihe:

Phenylalanin ($C_6H_5(CH_2 . CH . NH_2) . COOH$), Tyrosin ($C_6H_4(OH) . (CH_2 . CH . NH_2) . COOH$).

11. Zur Lehre von der Wirkung der Salze.

Zweite Mittheilung.

Von

Franz Hofmeister.

Ueber Regelmässigkeiten in der eiweissfällenden Wirkung der Salze und ihre Beziehung zum physiologischen Verhalten derselben.

Die Versuche, über welche S. Lewith vor Kurzem 1) berichtet hat, haben ergeben, dass jene Salze der Alkalien und der Magnesia, welchen das Vermögen zukommt, Eiweissstoffe in unverändertem Zustand aus ihrer Lösung auszufällen, im Blutserum zuerst das Globulin und erst nach dessen vollständiger Abscheidung das Albumin niederschlagen. Dieses Verhalten erwies sich als ein so regelmässiges, dass es vorläufig nicht nöthig erscheint, seine Gesetzmässigkeit durch Versuche mit noch nicht untersuchten Salzen weiter zu erhärten. Die Versuche Lewith's haben aber ferner gezeigt, dass die Sulfate und Acetate eine stärker fällende Wirkung entfalten, als die Chloride und Nitrate, und da die erstgenannten Salze zu den schwerer diffusiblen, mehr oder weniger stark abführend wirkenden Salzen gehören, während die an zweiter Stelle genannten als leicht diffusibel und diuretisch wirksam bekannt sind, so musste man daran denken, dass vielleicht zwischen dem Fällungsvermögen der Salze für Eiweiss und ihren physiologischen Eigenschaften eine gesetzmässige Beziehung besteht. Behufs Prüfung dieser Vermuthung war es nothwendig, zu ermitteln, ob der gefundene Parallelismus eine allgemeinere, über die wenigen von Lewith untersuchten Salze hinausreichende Geltung hat. Für den Fall, dass sich diese Ver-

Ueber die chemische Zusammensetzung der Peptone

von Dr. **Albrecht Kossel,** Assistenten am physiologisch-chemischen Institut zu Strassburg i. E.

(Der Redaktion übergeben am 24. Januar 1879.)

Maly [1]) und Henninger [2]) fanden für das aschefreie Fibrinpepton folgende Zusammensetzung:

	C	H	N
Maly	51,40	6,95	17,13
Henninger	51,58	7,02	16,66
	51,29	7,08	

während die Analysen [3]) der Chlor- und Calciumverbindung des Fibrinpeptons mich zu folgenden Zahlen für die Zusammensetzung des freien Peptons führten:

C	H	N	S
48,97	7,06	15,14	1,16

Die Differenzen zwischen beiden Werthen konnten auf verschiedene Weise erklärt werden. Entweder giebt das freie Pepton bei 110° chemisch gebundenes Wasser ab, während die Verbindung des Peptons dieses Wasser bei jener Temperatur zurückbehält, oder es entstehen bei der Pepsinverdauung anfangs Produkte, welche die von Maly und Henninger gefundene Zusammensetzung haben, später — durch weitere Hydratation — Produkte mit niederem Kohlenstoffgehalt. Für die erste Annahme spricht die von Hofmeister [4]) beobachtete Thatsache, dass beim Erhitzen des trockenen Peptons eine Anhydridbildung stattfindet, die zur Regeneration

Ueber die Peptone und ihr Verhältniss zu den Eiweisskörpern.

Von

Dr. **Albrecht Kossel,**
Assistent am physiol.-chem. Institut zu Strassburg.

Durch die Beobachtungen von Henninger [1]) und Hofmeister [2]) war die Frage nach der Natur der Pepsinwirkung zu einem gewissen Abschluss gekommen, es war gezeigt, dass die Verdauungsprodukte in ihrer Zusammensetzung nicht mit der des genuinen Eiweisskörpers übereinstimmen, dass die Bildung von Pepton aus Eiweiss durch Hydratation erfolgt und dass man aus dem Verdauungsprodukt durch wasserentziehende Mittel wieder Eiweis herstellen kann. Es war bewiesen, dass frühere Beobachtungen von Maly [3]) und Herth [4]) theilweise falsch gedeutet waren, dass ein Polymerie-Verhältniss zwischen Eiweiss und Pepton nicht existire, dagegen war eine von Schülern Hoppe-Seylers vertheidigte Ansicht im Princip anerkannt.

Es schien somit endlich Klarheit in jene bestrittene Frage gebracht zu sein, da erschien eine Abhandlung Maly's über Verwirrungen und Entstellungen in der Peptonlehre, deren Zweck ist, auf 16 Seiten „seinen Antheil an der Entwicklung der Peptonlehre, der vorläufig grösser ist, als der der übrigen Peptonbearbeiter zusammen, hervorzuheben" und deren Inhalt leider wirklich das bringt, was die Ueberschrift verspricht.

Maly's Schrift fordert dringend eine Entgegnung. Ich überlasse Andern ein Urtheil über die Berechtigung seiner Motive und über den Anstand seiner Polemik — in Folgendem sei der wissenschaftlichen Fehler dieses Autors gedacht. In die niederen

Ueber einen peptonartigen Bestandtheil des Zellkerns.

Von

A. Kossel.

(Der Redaktion zugegangen am 4. Juli 1884.)

Die rothen Blutkörperchen der Vögel bieten besonders günstige Verhältnisse für die chemische Untersuchung dar. Während die meisten der Analyse zugänglichen thierischen Organe aus verschiedenartigen Gewebssystemen zusammengesetzt sind, haben wir in den durch Senkung isolirten, rothen Blutkörperchen eine histologisch gleichartige Masse vor uns. Diese Gebilde haben hinsichtlich ihres Kerngehaltes noch den Charakter einer Zelle bewahrt, unterscheiden sich indess durch die Löslichkeit ihres Zellleibes in Wasser von den übrigen Gewebselementen. Der in Wasser unlösliche Theil besteht hauptsächlich aus dem Zellkern, daneben bleibt noch ein faseriges Gebilde («Stroma») zurück.

Die folgenden Untersuchungen, welche ich hauptsächlich im physiologisch-chemischen Institut zu Strassburg ausgeführt habe, wurden ausschliesslich an Gänseblut angestellt. Die in bekannter Weise isolirten Blutkörperchen wurden in Wasser unter Zusatz von Aether gelöst, die ungelöst bleibende Kernsubstanz mit Wasser bis zur vollständigen Entfärbung ausgewaschen. Wie die Untersuchungen von Plosz [1]) zeigten, enthält diese Masse reichlich Nucleïn. Dieselbe ist äusserst locker, mit dem Finger leicht zu zerdrücken. Bringt man sie in Alkohol, so schrumpft sie allmählich. Viel auffallender

Zur Kenntnis des Salmins.

Von

A. Kossel.

Die Protamine enthalten nach meinen früheren Untersuchungen neben den Gruppen des Arginins, Histidins und Lysins gewisse Monoamidosäuren. [1]) Die Verknüpfung dieser Gruppen ist, wie besonders die Biuretreaktion erweist, eine ähnliche, wie in den komplizierten Eiweißstoffen und ich habe auf meine Untersuchungen die Anschauung gegründet, daß die Protamine als die einfachsten bisher bekannten Glieder der Eiweißreihe aufzufassen sind; demgemäß habe ich mich bemüht, diese einfachen Eiweißkörper in ihrer Konstitution klarzustellen und hieraus Schlüsse auf die komplizierteren abzuleiten.

Eine systematische Betrachtungsweise der Eiweißkörper *ergibt sich, wenn man die den Protaminen zugrunde liegende,* durch die Untersuchungen von Goto genauer charakterisierte Protongruppe als Kern der einzelnen zum Eiweißmolekül vereinigten größeren Komplexe (Albumosen, Peptone) auffaßt. [2])

Dasjenige Spaltungsprodukt, welches die weiteste Verbreitung innerhalb dieser Körperklasse besitzt, und das keinem der bisher untersuchten Eiweißkörper fehlt: das Arginin ist aus den Protonen und Protaminen in reichlicher Menge zu gewinnen. Man wird durch die quantitativen Verhältnisse mit Wahrscheinlichkeit zu der Annahme geführt, daß in gewissen Fällen zwei Argininmoleküle miteinander vereinigt sind. Meine in Gemeinschaft mit F. Kutscher ausgeführte Untersuchung des Salmins hat ergeben, daß von 100 Teilen Stickstoff 87,8

226. Max Bergmann und Leonidas Zervas: Über ein allgemeines Verfahren der Peptid-Synthese.

[Aus d. Kaiser-Wilhelm-Institut für Lederforschung in Dresden.]
(Eingegangen am 18. Juni 1932.)

Die Eigenschaften der Proteine variieren mit der Art und der Reihenfolge der miteinander verknüpften Amino-säuren. Das Studium des gegenseitigen Einflusses der Amino-säure-Reste innerhalb der Peptid-Kette war bisher gehemmt durch die Unvollkommenheit unserer Verfahren zur Synthese von Peptiden. Von den klassischen Peptid-Synthesen Emil Fischers hat jene noch den weitesten Anwendungsbereich, die sich der Halogen-acyl-halogenide bedient[1]). Aber auch sie ist beschränkt auf die wenigen Amino-säuren, die aus Halogen-acylhalogeniden erhältlich sind. Wir suchten deshalb nach einem vielseitigeren Verfahren, das uns schon aus dem Grunde erwünscht war, weil die moderne Ferment-Chemie für ihre Untersuchungen über Wirkungsmechanismus und Spezifität der Peptidasen möglichst viele verschiedenartige Peptid-Kombinationen zur Verfügung haben muß.

Alle neueren Versuche zur Peptid-Synthese arbeiten nach folgendem Schema: Die Aminogruppe der ersten Amino-säure wird zuerst durch Einführung einer schützenden Atomgruppe R stabilisiert, dann wird das Carboxyl der Amino-säure so verändert, daß es zur Kuppelung mit einer zweiten Amino-säure befähigt wird, die Kuppelung wird vollzogen und schließlich die Atomgruppe R wieder abgespalten; damit liegt das fertige Peptid vor. Die Schwierigkeit liegt nun darin, eine geeignete Atomgruppe R zu finden, die sich am Schluß der Synthese so leicht wieder abspalten läßt, daß die Peptid-Bindung dabei nicht in erheblichem Maße angegriffen wird. Als Schutzgruppe R hat man Acetyl[2]) oder Toluolsulfonyl[3]) vorgeschlagen; aber ihre Anwendung hat bei der Peptid-Synthese nur zu vereinzelten Erfolgen geführt.

Viel allgemeinerer Anwendung fähig ist, wie wir im folgenden zeigen, der Rest $C_6H_5.CH_2.O.CO$ der Benzylester-kohlensäure, kurz Carbobenzoxy-Rest (Cbzo) genannt; denn er läßt sich mit Hilfe des leicht zugänglichen Chlorids $C_6H_5.CH_2.O.CO.Cl$ unschwer in Amino-säuren der verschiedensten Art einführen (Glykokoll-, *d*- und *d, l*-Alanin, *l*-Asparaginsäure, *l*-Asparagin, *d*-Glutaminsäure, *d*-Glutamin, *d, l*-Serin, *l*-Cystin, *d, l*-Phenyl-alanin, *l*-Tyrosin, *d*-Arginin, *l*-Histidin, ferner Glycyl-glycin) und — was das Wesentliche ist — durch einfache katalytische Hydrierung[4]) im offenen Gefäß in Form von Toluol und Kohlendioxyd wieder abspalten. Intermediär werden wohl Carbaminsäuren auftreten: $C_6H_5.CH_2.O.CO.NH.CH(R)COOH \rightarrow C_6H_5.CH_3 + HOCO.NH.CH(R).COOH \rightarrow CO_2 + NH_2.CH(R).COOH$. In ganz der gleichen Weise läßt sich der Rest der Benzylester-kohlensäure als Substituent der Aminogruppe aus Peptiden ent-

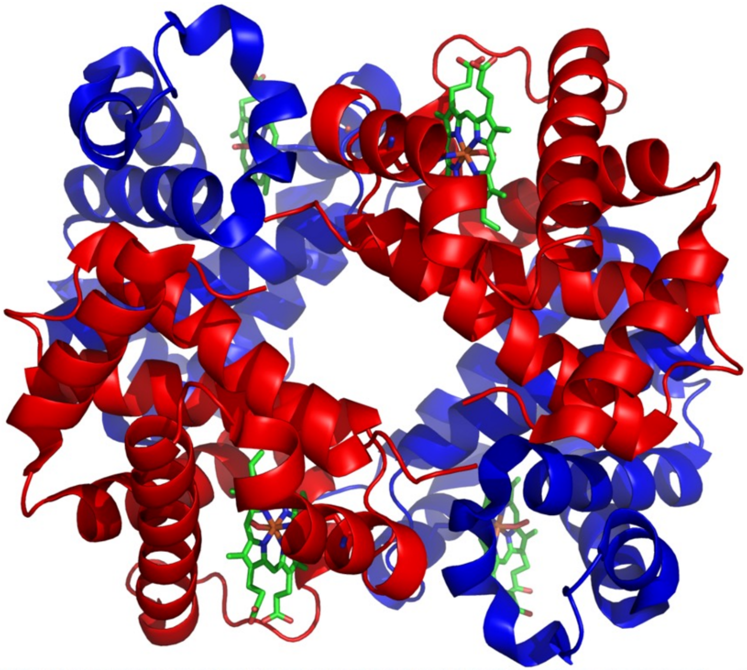
Max Perutz (1914–2002) developed and demonstrated methods of determining detailed 3D protein structures such as hemoglobin.



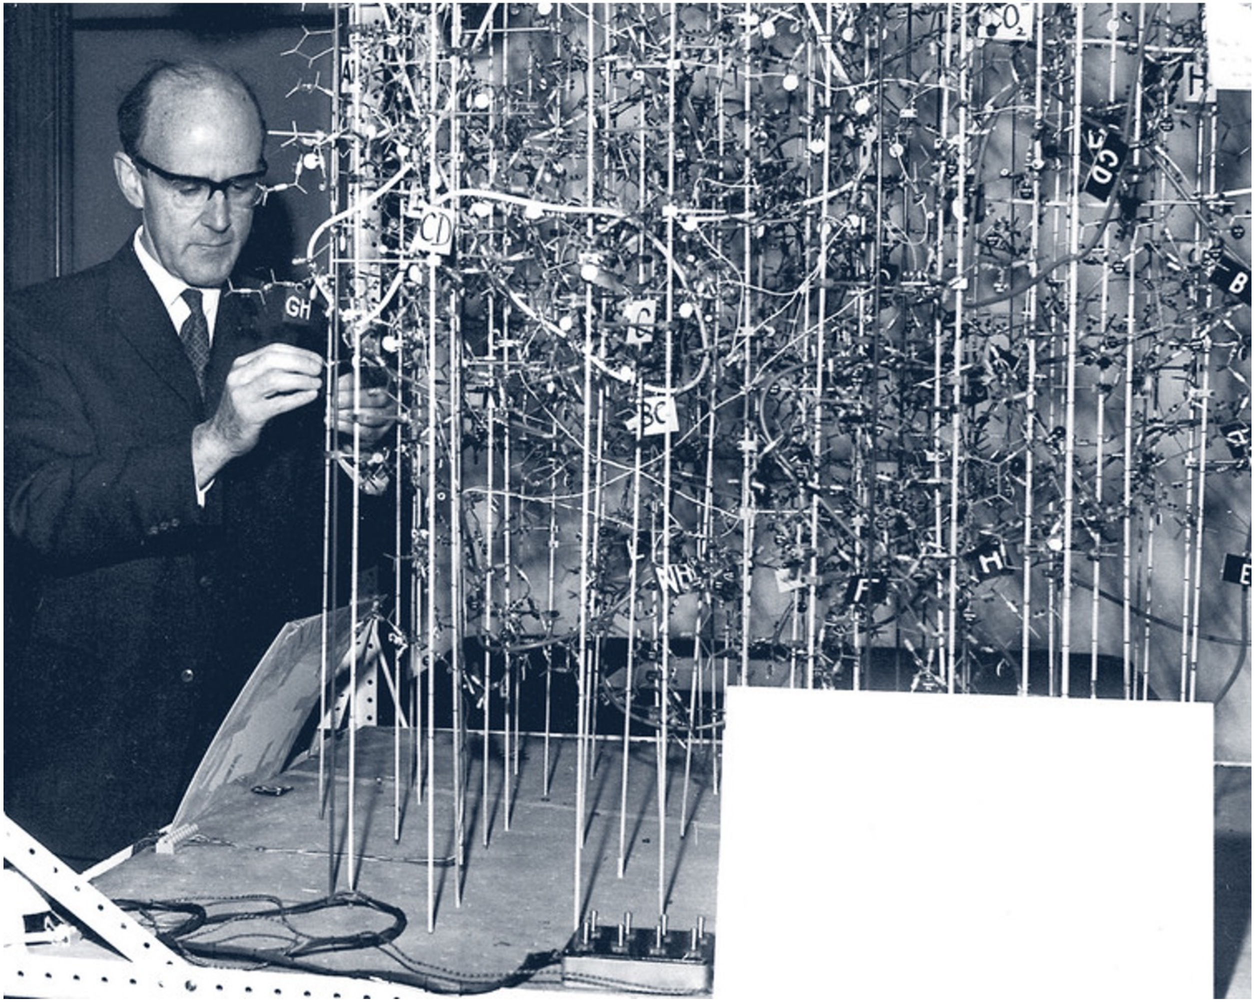


Figure 2.47: Max Perutz developed and demonstrated methods of determining detailed 3D protein structures such as hemoglobin.

2.1.5 Mitochondria, Cellular Respiration, and Metabolism

The creators discussed in this section worked on various aspects of the interrelated topics of mitochondria, cellular respiration, and other associated metabolic reactions:

- As illustrated in Figs. 2.48–2.49, mitochondria are the "power plants" within animal cells, plant cells, and fungi. In a process called cellular respiration, mitochondria carry out a series of chemical reactions to combine sugar and oxygen molecules to produce energy, carbon dioxide, and water.
- As shown in Fig. 2.50, the breaking down of sugars into half-sugars (such as pyruvate) and smaller molecules (glycolysis), and likewise the building up of sugars from smaller molecules (gluconeogenesis), involve many chemical steps, each carried out by a different enzyme.
- The Krebs or citric acid cycle within mitochondria converts half-sugars (containing carbon, hydrogen, and oxygen atoms) into hydrogens and carbon dioxide molecules. Each step is carried out by a different enzyme, as listed in Fig. 2.51.

German-speaking scientists played leading roles in discovering and understanding mitochondria, cellular respiration, and related metabolic reactions (Figs. 2.53–2.56).[10]

Justus von Liebig (German, 1803–1873, Fig. 2.55) was the first or one of the first scientists to propose the biochemical concept of cellular respiration.

Rudolf von Kölliker (Swiss, 1817–1905, Fig. 2.54) closely studied cells with high-resolution microscopes and discovered mitochondria sometime before 1888.

Completely independently, Richard Altmann (German, 1852–1900, Fig. 2.54) examined cells under the microscope and discovered mitochondria sometime before 1890.

In the 1910s, Fritz Pregl developed micro-pipetting and micro-analysis tools and methods that are now used in virtually all biology and chemistry laboratories [Pregl 1917]. See pp. 155 and 473. Pregl's micro tools and methods made it possible to conduct accurate measurements and manipulations of biochemical processes such as cellular respiration and fermentation, fundamentally enabling all of the other work in this field (and many other fields of biology and chemistry). Pregl won the Nobel Prize in Chemistry in 1923.

Gustav Embden (German, 1874–1933, Fig. 2.54), Otto Fritz Meyerhof (German, 1884–1951, Fig. 2.55), and Jakub Parnas (Austrian/Polish, 1884–1949, Fig. 2.55) discovered and explained what is now called the Embden-Meyerhof-Parnas pathway for glycolysis, the downward pathway on the left side of Fig. 2.50. They also conducted related research on muscle metabolism, liver biochemistry, and fermentation. For these discoveries, Meyerhof won the Nobel Prize in Physiology and Medicine in 1922. Professor J.E. Johansson, Chairman of the Nobel Committee for Physiology or Medicine, explained some of Meyerhof's research [https://www.nobelprize.org/prizes/medicine/1922/ceremony-speech/]:

> It is at this stage in the development of the question that Meyerhof's contribution comes in. In his investigations concerning the respiration of the tissues (1918) he came

---

[10] Deichmann 1996; Dominguez-Lacasa 2005; Gausemeier 2005; Gedeon 2006; Henry Harris 1999; Holmes 1993; Höxtermann and Sucker 1989; Jahn 2004; Junker 2004; Kohler 2008; Krebs 1981; 2005; Magner 2002; Perutz 1989, 1998; von Schwerin 2013; Simmons 2002 Stoff 2012.

> to devote his attention to the things that take place in the surviving muscle, and in this connection also to the objections that had been raised against the conclusions of Fletcher and Hopkins and their interpretation of the "lactic acid maximum" of the muscle. He showed that these objections do not really affect the result of the recently cited calculations of Hill. Most important of all, however, was his parallel determination of the lactic acid metabolism and the oxygen consumption during the recovery of the muscle, which yielded the result that the oxygen consumption does not correspond to more than 1/3–1/4 of the simultaneous lactic acid metabolism. Evidently the greater part of the lactic acid disappears in some other way than through combustion. In another parallel determination—the development of heat and the oxygen consumption—the development of heat exhibited a deficit in comparison with what could be calculated from the simultaneously observed oxygen consumption. From this the conclusion may be drawn that the combustion of lactic acid in the muscle is combined with some other process, an endothermic one, in the course of which part of the heat developed in the combustion is used up. Meyerhof also made a parallel determination of the carbohydrates and lactic acid in the resting and in the working muscle, also in the recovery period after fatigue; he found: when lactic acid is stored in the muscle, an equivalent quantity of carbohydrates, chiefly glycogen, disappears, while when lactic acid disappears, the quantity of carbohydrates in the muscle is increased by an amount equivalent to the difference between the total amount of lactic acid that has disappeared and the quantity oxidized corresponding to the oxygen consumption.
>
> Hence the processes which we have to take into account in the muscles are: (1) the formation of lactic acid from carbohydrates; (2) the combustion of lactic acid to carbonic acid and water; and (3) the reversion of lactic acid to carbohydrates. But these processes are not confined to the uninjured muscle. Meyerhof has also traced them in finely chopped muscle substance kept moist in a suitable liquid, and in that case found them take place 10–29 times more rapidly than in the well-known muscle preparation. In such a dilution it is also possible to study the effect of different factors such as the concentration of hydrogen ions, the presence of phosphates, etc.; and in particular it has been possible to make clear to what extent the various processes are connected with one another or can be varied in relation to one another. A matter of extremely great interest is the establishment of the fact that the combustion of lactic acid in the muscle cannot take place without a simultaneous formation of lactic acid from carbohydrates, and that the combustion of lactic acid is connected with the formation of carbohydrates in such a way that out of four molecules of lactic acid one is oxidized, while the three others are reverted to carbohydrates. lt is not inconceivable that the reversion does not always extend so far as to produce carbohydrates; but the ideal course of the process may be regarded as precisely defined by Meyerhof, and it has been represented by him in the form of a scheme of chemical reaction. In this scheme, too, can well be fitted the lactacidogen discovered by Embden as a connecting link between glycogen and lactic acid.

Otto Heinrich Warburg (German, 1883–1970, Fig. 2.56) studied many different aspects of cellular respiration during his long career, including the heme-based cytochrome reactions that harness energy taken from the Krebs cycle. He won the Nobel Prize in Physiology or Medicine in 1931 for some of his discoveries regarding the biochemical reactions in respiration. Professor E. Hammarsten of the Nobel Committee for Physiology or Medicine announced the award [https://www.nobelprize.org/prizes/medicine/1931/ceremony-speech/]:

> It had been known, since the days of Davy and Berzelius, that many metals possess the power of initiating or accelerating various reactions, including combustion. Starting from the possibility that had indeed been envisaged earlier, Warburg assumed that intracellular combustion might also be regarded as being due to catalysis by metals, i.e. that it might be initiated by some metallic compound. Definite proof that he was on the track of this well-hidden secret of Nature was obtained by the use of exact measurements of combustion in living cells or, as Warburg calls it, cell respiration. The quantitatively measured variations in the process of combustion under different conditions threw light on the nature of the respiratory ferment. Its tendency to enter into compounds with substances which combine with iron showed that it is itself an iron compound, and that its effects are due to iron. The correspondence between the effects of light on cellular combustion inhibited by carbon monoxide and on carbon-monoxide compounds of certain pigments closely related to blood pigments led, with the aid of a detailed mathematical analysis to the conclusion that the respiratory ferment is a red pigment containing iron, and that it is closely related to our own blood pigment. This was the first demonstration of an effective catalyst, a ferment, in the living organism, and this identification is the more important because it throws light on a process of general significance in the maintenance of life.
>
> Professor Warburg. From the start, your research has been focussed on problems of central importance. Your bold ideas, but above all, your keen intelligence and rare perfection in the art of exact measurement have won for you exceptional successes, and for the science of biology some of its most valuable material.
>
> I take the liberty of mentioning those two of your discoveries, which seem to be of the greatest value.
>
> The medical world expects great things from your experiments on cancer and other tumours, experiments which seem already to be sufficiently far advanced to be able to furnish an explanation for at least one cause of the destructive and unlimited growth of these tumours.
>
> Your discovery about the nature and effect of the ferment of respiration, which the Caroline Institute is rewarding this year with Alfred Nobel's Prize for Physiology or Medicine, has added a link of brilliant achievement to the chain that binds for all time[...]

Albert Szent-Györgyi (Hungarian, 1893–1986, Fig. 2.55) discovered several key components and reactions within the larger Krebs cycle, as well as the main biochemical steps involved in muscle contraction. He also won a Nobel Prize for his discoveries regarding vitamin C (p. 348). The *Encyclopedia Britannica* summarized his research [EB 2010]:

> Hungarian biochemist whose discoveries concerning the roles played by certain organic compounds, especially vitamin C, in the oxidation of nutrients by the cell brought him the 1937 Nobel Prize for Medicine or Physiology. [...]
>
> Szent-Györgyi then turned to the study of organic compounds known to play a part in the conversion of carbohydrate breakdown products to carbon dioxide, water, and

> other substances necessary for the production of usable energy by the cell. His work laid the foundations for Sir Hans Krebs's elucidation of the complete conversion cycle (the Krebs cycle) two years later.
>
> Devoting himself to a study of the biochemistry of muscular action, he discovered a protein in muscle that he named "actin," demonstrated that it—in combination with the muscle protein myosin—is responsible for muscular contraction, and showed that the compound adenosine triphosphate (ATP) is the immediate source of energy necessary for muscle contraction. Immigrating to the United States in 1947, he was immediately appointed director of the Institute for Muscle Research, Woods Hole, Mass., where he conducted research into the causes of cell division and, hence, cancer.

The married researchers Carl Cori (Austrian/Czech, 1896–1984) and Gerty Cori (Austrian/Czech, 1896–1957), shown in Fig. 2.53, discovered how the process of glycolysis could be reversed, gluconeogenesis (the upward pathway on the right side of Fig. 2.50). The coupled processes of glycolysis in muscle and gluconeogenesis in the liver are now called the Cori cycle. For their discoveries, Carl and Gerty Cori won the Nobel Prize in Physiology or Medicine in 1947. Professor H. Theorell of the Royal Caroline Institute explained the importance of their work [https://www.nobelprize.org/prizes/medicine/1947/ceremony-speech/]:

> After a great deal of preliminary work during the years 1932–1936, Professor Cori and his wife showed that if ground-up muscle was washed with water, the washed residue could still promote the disappearance of free phosphoric acid, which, as could be expected, was due to its being bound to sugar. But the washing had effected a change; the sugar phosphoric acid then formed exhibited certain singular properties. The Cori's were soon able to prove by means of crystallization and determination of the constitution of the new compound that the characteristic properties of this phosphoric acid ester, the so-called Cori ester were due to the fact that phosphoric acid was linked to the first carbon atom of the sugar instead of to its sixth. A layman would probably think that such a detail could only be of interest for hairsplitting specialists; but the grain of mustard seed may grow up into a great tree, if it is sown in suitable soil. From this apparently insignificant startingpoint the Cori's and their co-workers, in a long series of masterly studies, have thrown clear light on the previously unknown interplay between glucose, phosphoric acid and glycogen. The reason why the Cori ester is found only in *washed* muscle is that with the washing water an enzyme is removed, i.e. a protein substance with a special catalytic effect, which moves phosphoric acid from one end of the sugar molecule, the 1-position to the opposite, the previously known 6-position.
>
> An enzyme crystallized by the Cori's and Green, phosphorylase, plays a chief part in the mechanism. It is met with in many different tissues and can be prepared from, e.g., muscle, liver or yeast. If the phosphorylase is allowed to act on glycogen in the presence of phosphoric acid, the whole glycogen molecule is split up, with the simultaneous appearance of glucose molecules bound to phosphoric acid. This substance is indeed the Cori ester. The same process may, however, also proceed in the opposite direction, so that glycogen is formed from the Cori ester. The direction of the reaction is determined by the relative amounts of the components. For glycogen synthesis to start, a small amount of glycogen must be present as a nucleus upon which to build. Thus, if under extreme conditions it should happen that all the glycogen were broken down, the individual in question would lose for all time the capacity to form glycogen. Such

> a thing cannot happen, however, thanks to an ingenious protective mechanism discovered by the Cori's. When the glycogen supply threatens to come to an end, an enzyme intervenes, which for the time being inactivates the glycogen-splitting phosphorylase and thus preserves the last traces of the glycogen. Nature's wealth of invention is truly amazing!
>
> For a chemist, synthesis is the definite proof of how a substance is built up. Professor and Doctor Cori have accomplished the astounding feat of synthesizing glycogen in a test tube with the help of a number of enzymes which they have prepared in a pure state and whose mode of action they have revealed. This synthesis would be impossible by methods of organic chemistry alone, since the six carbon atoms of the various glucose molecules might conceivably be bound to one another in a chaotic mass of combinations. The Cori enzymes made this synthesis possible, because the enzymes favour certain modes of linkage. In spite of this, the difficulties were formidable; the first isolated phosphorylases formed unbranched compounds resembling starch, and only with the help of further enzymes were the branched chains characteristic of glycogen obtained.
>
> Blood and tissues contain free glucose. The chemical changes in metabolism are always initiated by its being coupled to phosphoric acid, which is transferred from a nitrogenous phosphoric acid compound usually called ATP. The reaction is promoted by the enzyme *hexokinase*. Two years ago a great sensation was aroused in the scientific world when the Cori's, together with Price, Colowick and Slein, announced that this hexokinase reaction was promoted by insulin but checked by another hormone in extracts from the anterior lobe of the pituitary gland, the hypophysis. The experiments have been confirmed and extended this year. This discovery is of fundamental significance. We have long known that the secreting organs—the pituitary gland, the thyroid gland, the accessory thyroid glands, the suprarenal glands, the pancreas, the sex-glands, and a number of others—exercise a decisive influence on our vital functions. But the perpetual question, which we meet already in Luther's catechism: "How does it take place?" has remained unanswered until the discovery—published by Cori's Institute—that hormones intervene chemically in the hexokinase reaction. A wide new field of physiology was thereby linked up with the domain of chemistry. In the near future it will be possible to express a further part of the mystical "vital force" in chemical formulae.

Karl Lohmann (German, 1898–1978, Fig. 2.55) discovered adenosine triphosphate (ATP) in 1929. Mitochondria convert the energy stored in sugar molecules to energy stored in ATP molecules. ATP is then used as an energy source to power a wide variety of enzymes and other processes inside cells.

Fritz Lipmann (German, 1899–1986, Fig. 2.55) discovered coenzyme A, which plays critical roles both in the Krebs cycle and in the synthesis and consumption of fats. For this accomplishment, he won the Nobel Prize in Physiology or Medicine in 1953. Professor E. Hammarsten of the Royal Caroline Institute noted [https://www.nobelprize.org/prizes/medicine/1953/ceremony-speech/]:

> [...] Lipmann announced his discovery of coenzyme A. Now suddenly everything fitted perfectly—the last notch of a combination lock fell into its place.
>
> Coenzyme A is a compound with a rather small molecule, which, when united with the enzyme-protein, acquires the property of binding acetic acid. Acetic acid is normally

> quite unreactive but when bound in this way it becomes labile and reactive and represents the previously mystical 2-carbon compound which combines with a 4-carbon compound to form citric acid. A new way for the transmission of energy in the cell was demonstrated by this discovery.
>
> Recently the acetyl phosphate made a come-back, when Lipmann with his usual keen insight showed that it is used as the active 2-carbon compound in certain bacteria. Far from feeling triumphant Lipmann wrote in his otherwise very serious scientific paper that he was quite happy about this finding.
>
> That Lipmann's discovery has an even wider scope became clear when he and others found that other acids than acetic acid are activated by coenzyme A bound to other enzyme proteins.

Hans Adolf Krebs (1900–1981, Fig. 2.54) combined the results of his own experimental investigations with those from earlier researchers to work out the complete Krebs cycle, or citric acid cycle. He won the Nobel Prize in Physiology or Medicine in 1953, and Professor E. Hammarsten of the Royal Caroline Institute praised the scientific insight of Krebs [https://www.nobelprize.org/prizes/medicine/1953/ceremony-speech/]:

> It was Krebs who discovered how these individual reactions are linked to each other in a cyclic process. He brought us a clear understanding of the essential principle of how the released energy is used for the building up processes which take place within the cell.
>
> This energy is liberated by the oxidation of a 2-carbon compound to carbonic acid and water. This 2-carbon compound is derived from the foodstuffs and is introduced into the Krebs cycle. The nature of this compound and the mechanism of its incorporation were discovered by Fritz Lipmann. But for the moment let us not be concerned with this discovery since at that time it had not yet been made. In the beginning Krebs was quite alone with his idea, and when he first presented it, it was criticized by many. But soon he found an even greater number of supporters who were joined by his previous critics. Krebs' idea was that the mysterious 2-carbon compound is added on to a known substance with 4 carbon atoms yielding a 6-carbon compound. The 2-carbon compound, bound in this way, is then degraded stepwise to carbonic acid, water, and energy. When this degradation is completed, the 4-carbon compound is again free to react with another 2-carbon molecule, which starts a new period in the oxidation cycle. Krebs could show that the 6-carbon compound formed at the onset of this cycle is citric acid which contains three carboxyl groups. The cycle is therefore also called the tricarboxylic acid cycle. [...]
>
> Out of the chaos of isolated reactions Krebs succeeded in extracting the basic system for the essential pathway of oxidation process within the cell. His penetrating intuition was so clear and true and his grasp of the problem so keen from the start that none of his original ideas had to be revised.

Hans Kornberg (German, 1928–, Fig. 2.54) received his Ph.D. under Hans Krebs. Together, Kornberg and Krebs discovered the glyoxylate cycle, an alternate version of the Krebs cycle that occurs in some microorganisms and plants.

platte auf, mit der trichterförmigen Erweiterung nach oben, so wird die axiale Bohrung derselben unten durch die Grundplatte abgeschlossen. Durch Einbringen der Substanz in das Bohrloch von der trichterförmigen Erweiterung aus und einmaliges Nachstopfen mit dem in die Bohrung genau passenden Zapfen des mit Griff ausgestatteten Stopfers gelingt es, durch verhältnismäßig leichten Handdruck eine fest zusammenhaltende Pastille in den Raum zu pressen. Um sie aus der Pastillenkammer zu entfernen (Fig. 35c), schiebt man einen 8 mm breiten Metallring zwischen die Grundplatte und die die Pastille in ihrem Innern tragende Platte, stößt die Pastille mit einem kurzen Schlag auf den Stopfer durch, worauf sie innerhalb des Ringes auf die Grundplatte zu liegen kommt.

Erfahrungsgemäß empfiehlt es sich, in dieser Weise Pastillen im Gewichte von 7, höchstens 10 mg anzufertigen. Sie werden in Substanzröhrchen, wie sie bei der Stickstoffbestimmung Verwendung finden, mit einer Genauigkeit von nur 0,01 mg gewogen und die erste sofort in den Apparat eingetragen, sobald der Siedepunkt konstant geworden ist. Nach erfolgter Lösung steigt der Siede-

2.2 Microbiology and Immunology

Microbiology covers different categories of microorganisms, most of which include important pathogenic and nonpathogenic examples. German-speaking scientists made large numbers of important discoveries for all categories of microorganisms, as well as in the immunology:

> 2.2.1. Bacteria are individual prokaryotic (simple) cells that can reproduce themselves, but often like to live on the nutrients available inside a host organism (such as a person).
>
> 2.2.2. Viruses are rogue genes (generally packaged with other components) that need to hijack a cell to reproduce.
>
> 2.2.3. Prions are rogue proteins that need to hijack a cell to reproduce.
>
> 2.2.4. Fungi are small eukaryotic (complex) cells, surrounded by cell walls but otherwise not unlike eukaryotic animal cells.
>
> 2.2.5. Protozoa are simple animals composed of a single eukaryotic cell.
>
> 2.2.6. Helminths are multi-celled eukaryotic worms that start off like microorganisms but may grow to significant size.
>
> 2.2.7. Immunology, a closely related topic, is how the cells and proteins that make up the body's immune system fight infections by pathogenic microorganisms.

As a supplement to the material in this section, Appendix A gives information on offensive biological weapons research that may have been conducted in the Germany during World War II (as opposed to merely defensive work, aimed at protecting against biological weapons).[11] According to official histories, Germany did not pursue biological weapons during World War II. However, Appendix A presents evidence that suggests that Germany may have actually made major advances in biological warfare research and development during this time, and that German-speaking scientists may have subsequently transferred those methods and materials to postwar biological warfare programs in the United States, the Soviet Union, and other countries. While bioweapon development may not be viewed as an honorable field of research (harnessing microbiological knowledge to cause diseases instead of to cure them), the revolutionary nature of the actual science is noteworthy, and the long-term impact on Cold War military programs, modern concerns about bioterrorism, and even research on clinical pathogens and therapeutics has been profound. Many details remain murky and further historical investigation is definitely needed.

2.2.1 Bacteria

Bacteriology is the study of bacteria and the infections they can cause. The upper part of Fig. 2.57 shows the structure of a typical bacterium or prokaryotic cell. It is in the range of 0.5-5 μm (microns or millionths of a meter) long, near the limit of what can be readily seen with an optical microscope and roughly 10 times smaller than human and other eukaryotic (complex) cells; that is why microbiology in the German-speaking world was greatly aided by improvements in microscopes that also occurred in the German-speaking world (Section 6.9).

Prokaryotic cells are surrounded by a plasma membrane (like eukaryotic cells), but for extra protection against harsh environmental conditions or attack by a host's immune system, they add a sturdy cell wall and then for some bacteria also a capsule of polysaccharide slime. Different categories of bacteria have different types of cell walls, as illustrated in Figs. 2.57 (bottom) and 2.58.

While there were certainly contributions from scientists elsewhere (most notably Louis Pasteur (French, 1822–1895), who was personally responsible for a long list of revolutionary discoveries), scientists in the greater German-speaking world arguably played the greatest role in the development of bacteriology.[12]

Antonie van Leeuwenhoek (Dutch, 1632–1723) created the first known microscope and used it to observe a variety of microscopic organisms. In 1762, Marcus Antonius von Plenciz (Austrian, 1705–1786) published a book, *Opera medico-physica*, in which he persuasively argued that many diseases were caused by microorganisms, and he even divided those diseases into different categories by how the organisms were apparently spread. Friedrich Henle (Bavarian, 1809–1885) also publicly advocated for the germ theory of disease in 1840; one of his students was Robert Koch, who went on to make countless contributions to bacteriology.

Gram - (e.g., *Borrelia*)

Figure 2.58: Bacteria may be classified by both their cell wall type and their shape: cocci or spherical bacteria, bacilli or rod-shaped bacteria, and spirochetes or spiral-shaped bacteria. Bacteria may also be connected in different ways: individual bacteria, joined pairs [diplo-], chains [strepto-] of bacteria, and clumps [staphylo-] of bacteria.

In 1847, Ignaz Semmelweis (Austrian, 1818–1865, Fig. 2.59) went further than these earlier scientists by introducing and demonstrating the importance of antiseptics (especially a dilute solution of calcium hypochlorite or bleach) in preventing the spread of disease-causing organisms, such as a *Streptococcus* strain that was causing puerperal fever or “childbed fever” in Vienna hospitals at the time. Semmelweis demonstrated that his antiseptic methods greatly reduced infection rates at the hospitals where he worked, yet he struggled the rest of his life to persuade hospitals elsewhere of the importance of antiseptics. Two decades later, in 1867, Joseph Lister (British, 1827–1912) published similar results and achieved far more more success and fame in promoting antiseptics, specifically phenol or “carbolic acid” as he called it. Ironically, phenol soon fell out of favor as an antiseptic due to its toxicity, whereas Semmelweis’s preferred solution of dilute hypochlorite bleach is still widely used to disinfect surfaces and linens in hospitals.

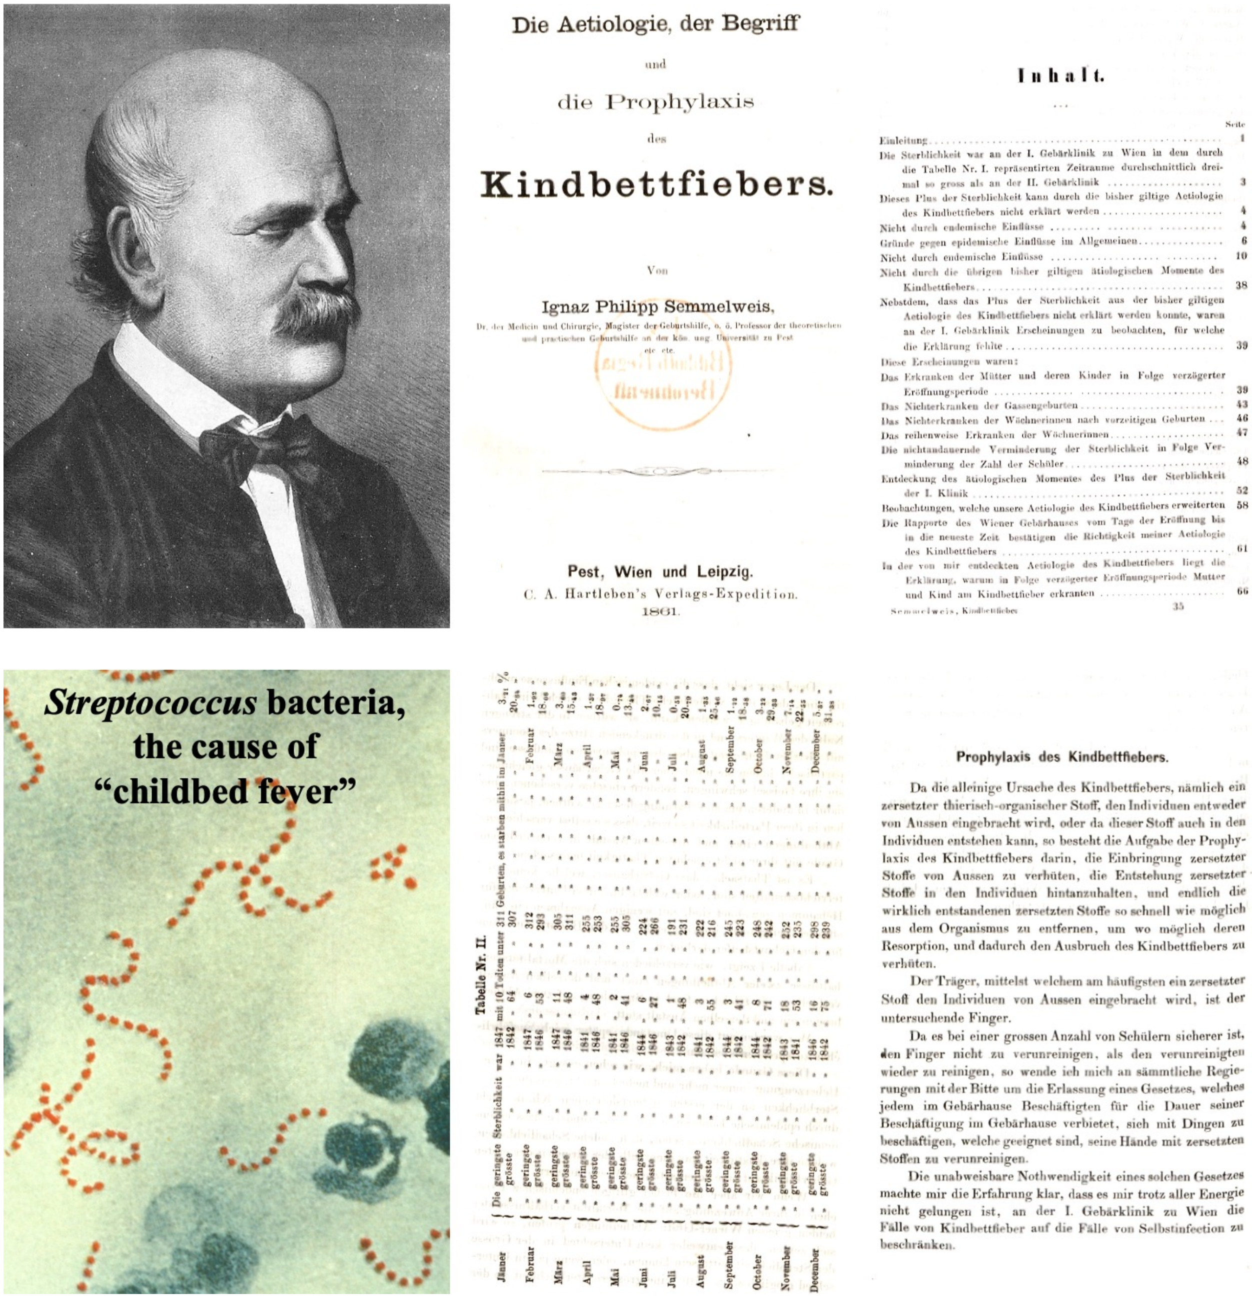
With newly improved microscopes (Section 6.9), it became much easier to see organisms as small as bacteria. However, a remaining problem was that most bacteria are essentially clear, and surrounded by essentially clear liquid or other sample material. Therefore, scientists in the German-speaking world developed methods that stained bacteria different colors than the surrounding sample material, making it much easier to visualize their shapes and identify them under the microscope. Scientists who developed important early microscope staining techniques for bacteria included Karl Weigert (German, 1845–1904), Paul Ehrlich (German, 1854–1915), and Robert Koch (German, 1843–1910), as shown in Fig. 2.60.

In 1872, Ferdinand Cohn (German, 1828–1898, Fig. 2.61) created the modern classification system for bacterial shapes (spheres or cocci, rods or bacilli, spirals or spirochetes, etc.).

Based on the earlier stains, Hans Christian Gram (Danish but worked and made his discovery in Germany, 1853–1938, Fig. 2.60) developed the “Gram staining” method in Berlin in 1884 while working with Carl Friedländer (German, 1847–1887, Fig. 2.65). Gram staining is still widely used to distinguish between bacteria with two different types of cell walls, “Gram-positive” bacteria that turn purple with this technique and “Gram-negative” bacteria that turn red. The ability to distinguish between Gram-positive and Gram-negative bacteria, and among bacteria with different shapes, was and remains a powerful method to identify bacteria under the microscope (Fig. 2.58).

Ignaz Semmelweis (1818–1865) developed and demonstrated antiseptics to prevent bacterial infections (1847).

Semmelweis made his discovery nearly two decades before Joseph Lister's much better known work (1865), and Semmelweis's chlorine-bleach-based solution was safer and more modern than Lister's phenol solution.



Die Aetiologie, der Begriff
und
die Prophylaxis
des
Kindbettfiebers.

Von
Ignaz Philipp Semmelweis,
Dr. der Medicin und Chirurgie, Magister der Geburtshilfe, ö. ö. Professor der theoretischen und practischen Geburtshilfe an der kön. ung. Universität zu Pest
etc. etc.

Pest, Wien und Leipzig.

Einleitung 1
Die Sterblichkeit war an der I. Gebärklinik zu Wien in dem durch die Tabelle Nr. I. repräsentirten Zeitraume durchschnittlich dreimal so gross als an der II. Gebärklinik 3
Dieses Plus der Sterblichkeit kann durch die bisher giltige Aetiologie des Kindbettfiebers nicht erklärt werden 4
Nicht durch endemische Einflüsse 4
Gründe gegen epidemische Einflüsse im Allgemeinen 6
Nicht durch endemische Einflüsse 10
Nicht durch die übrigen bisher giltigen ätiologischen Momente des Kindbettfiebers 38
Nebstdem, dass das Plus der Sterblichkeit aus der bisher giltigen Aetiologie des Kindbettfiebers nicht erklärt werden konnte, waren an der I. Gebärklinik Erscheinungen zu beobachten, für welche die Erklärung fehlte 39
Diese Erscheinungen waren:
Das Erkranken der Mütter und deren Kinder in Folge verzögerter Eröffnungsperiode 39
Das Nichterkranken der Gassengeburten 43
Das Nichterkranken der Wöchnerinnen nach vorzeitigen Geburten . . . 46
Das reihenweise Erkranken der Wöchnerinnen 47
Die nichtandauernde Verminderung der Sterblichkeit in Folge Verminderung der Zahl der Schüler 48
Entdeckung des ätiologischen Momentes des Plus der Sterblichkeit der I. Klinik 52
Beobachtungen, welche unsere Aetiologie des Kindbettfiebers erweiterten 58
Die Rapporte des Wiener Gebärhauses vom Tage der Eröffnung bis in die neueste Zeit bestätigen die Richtigkeit meiner Aetiologie des Kindbettfiebers 61
In der von mir entdeckten Aetiologie des Kindbettfiebers liegt die Erklärung, warum in Folge verzögerter Eröffnungsperiode Mutter und Kind am Kindbettfieber erkranten 66

Semmelweis, Kindbettfieber 35

Prophylaxis des Kindbettfiebers.

Da die alleinige Ursache des Kindbettfiebers, nämlich ein zersetzter thierisch-organischer Stoff, den Individuen entweder von Aussen eingebracht wird, oder da dieser Stoff auch in den Individuen entstehen kann, so besteht die Aufgabe der Prophylaxis des Kindbettfiebers darin, die Einbringung zersetzter Stoffe von Aussen zu verhüten, die Entstehung zersetzter Stoffe in den Individuen hintanzuhalten, und endlich die wirklich entstandenen zersetzten Stoffe so schnell wie möglich aus dem Organismus zu entfernen, um wo möglich deren Resorption, und dadurch den Ausbruch des Kindbettfiebers zu verhüten.

Der Träger, mittelst welchem am häufigsten ein zersetzter Stoff den Individuen von Aussen eingebracht wird, ist der untersuchende Finger.

Da es bei einer grossen Anzahl von Schülern sicherer ist, den Finger nicht zu verunreinigen, als den verunreinigten wieder zu reinigen, so wende ich mich an sämmtliche Regierungen mit der Bitte um die Erlassung eines Gesetzes, welches jedem im Gebärhause Beschäftigten für die Dauer seiner Beschäftigung im Gebärhause verbietet, sich mit Dingen zu beschäftigen, welche geeignet sind, seine Hände mit zersetzten Stoffen zu verunreinigen.

Die unabweisbare Nothwendigkeit eines solchen Gesetzes machte mir die Erfahrung klar, dass es mir trotz aller Energie nicht gelungen ist, an der I. Gebärklinik zu Wien die Fälle von Kindbettfieber auf die Fälle von Selbstinfection zu beschränken.

Figure 2.59: Ignaz Semmelweis discovered the importance of antiseptics in preventing the spread of pathogens, such as a *Streptococcus* strain that caused "childbed fever."

No. 6. | Diese Zeitschrift erscheint am 1. und 15. jeden Monats. Abonnement für den Jahrg. von 24 Nummern M. 20. | 15. März.

Original-Mittheilung.

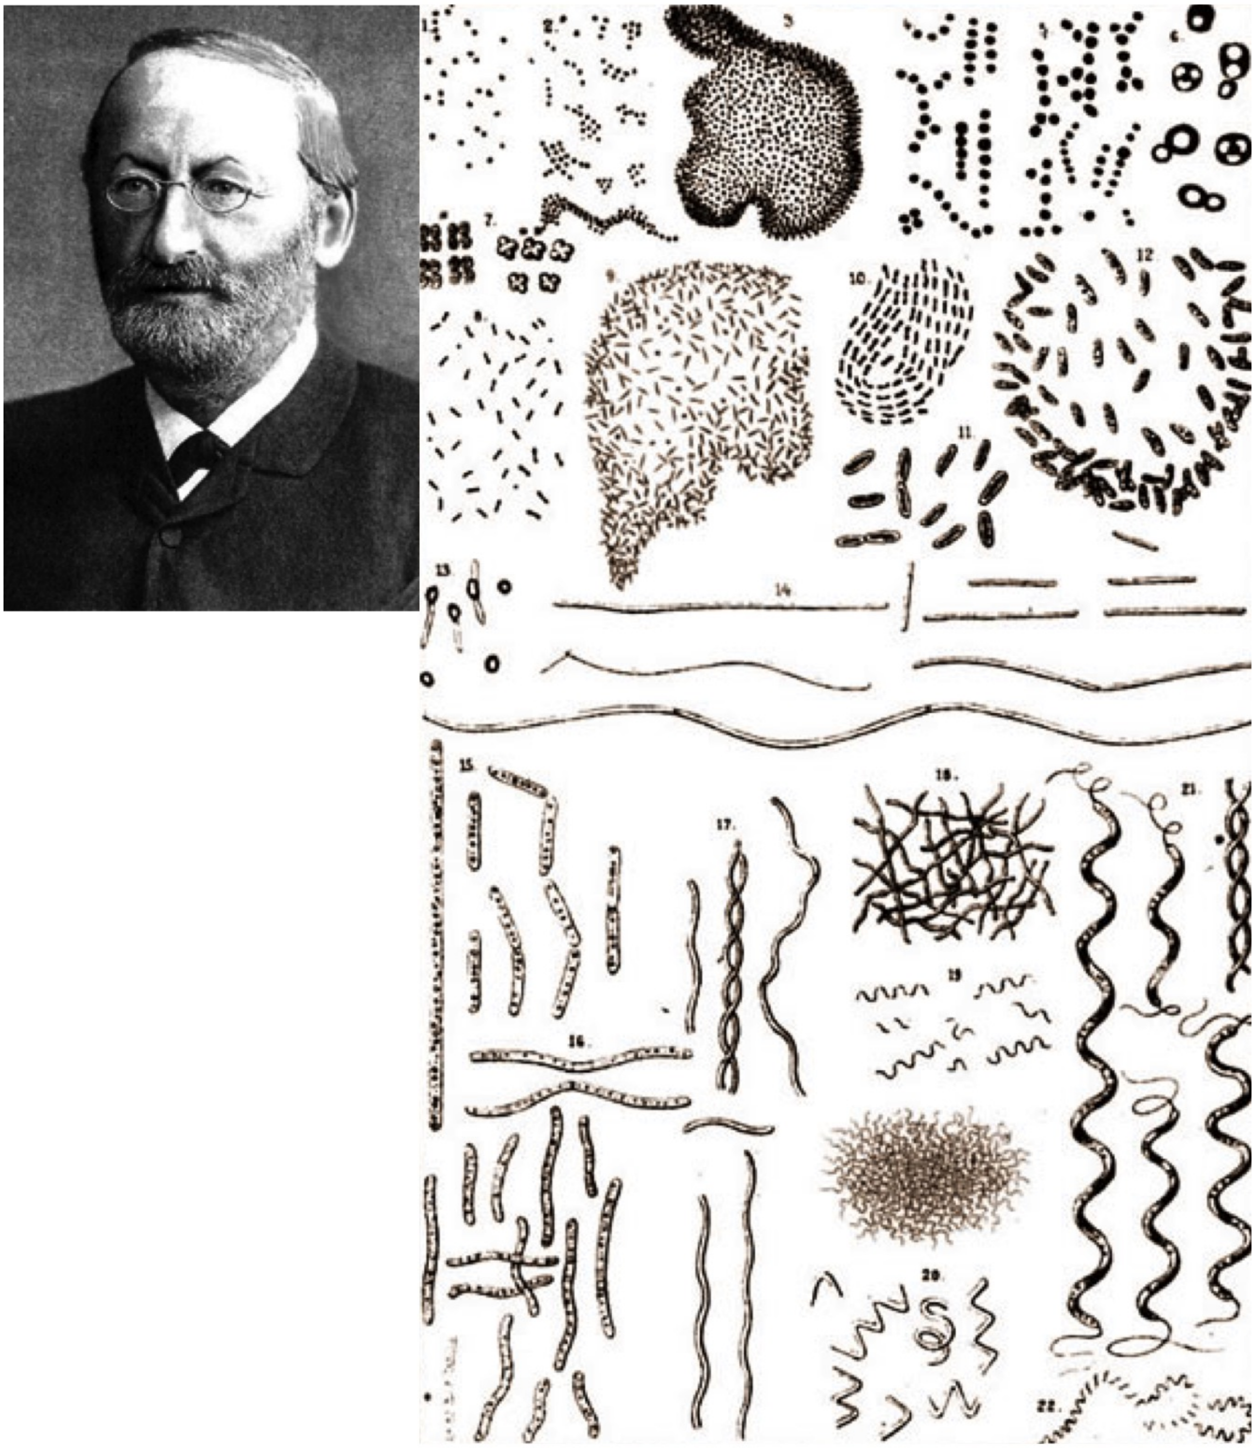
Ueber die isolirte Färbung der Schizomyceten in Schnitt- und Trockenpräparaten.

Von Dr. C. Gram aus Kopenhagen.

(Die Gelegenheit und den grössten Theil des Materials zu den folgenden Untersuchungen verdanke ich Hrn. Dr. Riess, Director des städt. allgem. Krankenhauses in Berlin.)

Wie bekannt giebt die Methode der isolirten Färbung der Tuberkelbacillen von Koch und Ehrlich mit oder ohne Doppelfärbung sehr schöne Bilder, weil die Bacillen durch die Contrastwirkung sehr deutlich hervortreten.

Figure 2.60: Creators who developed methods of staining bacteria to identify them under the microscope included Karl Weigert, Paul Ehrlich, Robert Koch, and Hans Christian Gram. Gram staining is still widely used to distinguish between bacteria with two different types of cell walls, "Gram positive" bacteria that turn purple and "Gram negative" bacteria that turn red.



Ferdinand Cohn (1828–1898) established the modern categories for bacteria shapes (1872)

Figure 2.61: Ferdinand Cohn established the modern categories for bacteria shapes.

As soon as German-speaking scientists developed improved microscopes and staining techniques for bacteria, those and other German-speaking scientists immediately began to use those methods to identify the bacteria responsible for different diseases. In fact, German-speaking scientists identified almost all of the bacteria that were responsible for major bacterial infections at that time:

- Theodor Escherich (German/Austrian, 1857–1911, Fig. 2.62) discovered the common intestinal bacteria *Escherichia coli* (*E. coli*) in 1885. Some strains of *E. coli* produce toxins and cause food-borne disease outbreaks. Nonpathogenic *E. coli* are now widely used as genetically engineered "workhorses" in biotechnology.

- Albert Fraenkel (German, 1848–1916, Fig. 2.62) discovered *Streptococcus pneumoniae*, the cause of bacteria pneumonia, in 1884.

- Alexandre Yersin (Swiss, 1863–1943, Fig. 2.62) discovered *Yersinia pestis* bacteria, the cause of bubonic, pneumonic, and septicemic plague, in 1894.

- Robert Koch (Fig. 2.63) discovered *Bacillus anthracis*, the cause of anthrax, in 1877; *Staphylococcus* strains, the cause of staph skin infections, in 1878; *Mycobacterium tuberculosis*, the cause of tuberculosis, in 1882; and *Vibrio cholerae*, the cause of cholera, in 1883. Koch received the Nobel Prize in Physiology or Medicine in 1905.

  Professor the Count K. A. H. Mörner, Rector of the Royal Caroline Institute, went into detail about Koch's achievements [https://www.nobelprize.org/prizes/medicine/1905/ceremony-speech/]:

  > In 1876 Koch entered the field of bacteriological research with an investigation of anthrax, and two years later he produced his classical investigations into diseases from wound infections. With the views set out there and the way he formulated the questions, he had a fundamental effect on the further development of bacteriology, and the ideas he expressed there recur as a leading motive in his subsequent research and form the foundation of modern bacteriology, as they do of the axioms of hygiene which are derived from it.
  >
  > He stressed that, if bacteria caused a disease, then they must always be demonstrable in it, and they should develop in a way such that this would account for the pathological process.
  >
  > He further stressed that the capacity to produce disease could not be a general property of bacteria or one common to them all. On the contrary it should be expected in this respect to find specific properties distinguishing individual bacteria. Even if they resemble other bacteria in their form, etc. they must still be different from one another by virtue of this biological property: in other words, every disease must have its special bacterium, and to combat the disease, it would be necessary to look for clues in the biology of the bacterium. Koch therefore not only set himself the task of examining the problem of whether diseases were caused by bacteria, but also endeavoured to discover the special micro-organisms of the particular diseases and to get to know more about them: this was a problem which, in the circumstances then prevailing, seemed to offer very little hope of being solved. In the way Koch solved this problem he was just as much, if not more, of a pioneer, then he already

was in the abovementioned precision which he had given to the formulation of the problem.

To start with, developing a general methodology is as valuable as finding the correct technique for every special case. Koch's genius has blazed new trails in this respect and has given present-day research its form. To give a detailed description of this is beyond the scope of this account. I only want to mention that he had moreover already given a significant development to techniques in staining and microscopic investigation as well as in the field of experiment in his earliest work. Shortly after this he produced the important method, which is still generally the usual one, of spreading the material under investigation in a solid nutrient medium to allow each individual among the micro-organisms present to develop into a fixed colony, from which it is possible, in further research, to go on to obtain what is known as a pure culture.

Shortly after the publication of his investigations into diseases from wound infections Koch was appointed to the new Institution, the "Gesundheitsamt" (Department of Health), in Berlin. There he started work on some of the most important human diseases, namely, tuberculosis, diphtheria and typhus. He worked on the former one himself. The two latter investigations he left to his first two pupils and assistants, Loeffler and Gaffky. For all three diseases the specific bacteria were discovered and studied in detail.

To give an account of the work which Koch carried out, or accomplished through his pupils, and also to mention the work which derives more indirectly from Koch, would nearly be the same as describing the development of bacteriology over the last few decades. I will content myself with naming some of the most important discoveries and items of research which, in addition to those already named, are more directly linked with Koch's name. At the head of the German Cholera Commission Koch investigated the parasitic aetiology of cholera in Egypt and India, and discovered the cholera bacillus and the conditions necessary for its life. Experience thus gained found practical application in the development of measures taken to prevent and combat this devastating disease. In addition Koch made important investigations concerning plague in humans, malaria, tropical dysentery, and the Egyptian eye disease (trachoma) among others, and now finally concerning typhus recurrens in tropical Africa. He has also carried out work of exceptional importance, concerning a host of destructive tropical cattle diseases, such as rinderpest, Surra disease, Texas fever, and finally concerning coast fever in cattle and the trypanosome disease carried by the tsetse fly.

Through the perfection he gave to methods of culturing and identifying micro-organisms, he has been able to carry out his work with regard to disinfectants and methods of disinfection so important for practical hygiene, and advice concerning the early detection and combating of certain epidemic diseases such as cholera, typhus and malaria.

- Arthur Nicolaier (German, 1862–1942) discovered *Clostridium tetani*, the cause of tetanus, in 1884. Émile van Ermengem (Belgian but closely coupled to the German research world, 1851–1932) discovered the closely related *Clostridium botulinum*, the cause of botulism, in 1896. See Fig. 2.64.

- Carl Friedländer and T. A. Edwin Klebs (German, 1834–1913) discovered *Klebsiella pneumoniae*, a cause of bacterial pneumonia, in 1882. See Fig. 2.65.

- T. A. Edwin Klebs and Friedrich Löffler (German, 1852–1915) discovered *Corynebacterium diptheriae*, the cause of diptheria, in 1883. See Fig. 2.65.

- Albert Neisser (German, 1855–1916) discovered *Neisseria gonorrhoeae*, the cause of gonorrhea, in 1879. Anton Weichselbaum (Austrian, 1845–1920) discovered the closely related *Neisseria meningitidis*, the cause of bacterial meningitis, in 1887. See Fig. 2.66.

- Erich Hoffmann (German, 1868–1959) and Fritz Schaudinn (German, 1871–1906) discovered *Treponema pallidum*, the cause of syphilis, in 1903. See Fig. 2.66.

- *Salmonella* species cause various illnesses (Fig. 2.67). Karl Joseph Eberth (German, 1835–1926) discovered *Salmonella typhi*, the cause of typhoid fever, in 1880; Georg Gaffky (German, 1850–1918) confirmed that finding in 1884. August Gaertner (1848–1934) discovered *Salmonella enteritidis*, the cause of salmonellosis, in 1888. Hugo Schottmüller (German, 1867–1936) discovered *Salmonella paratyphi*, the cause of paratyphoid fever, in 1900.

German-speaking scientists also developed methods to cultivate bacteria and other microorganisms, as shown in Figs. 2.68–2.73:

- Working together with Robert Koch, Julius Petri (German, 1852–1921) invented Petri dishes in 1881. In that same year, spouses Fanny Hesse (born of German parents in the United States, lived in Germany, 1850–1934) and Walther Hesse (German, 1846–1911) developed agar nutrient gel to fill those dishes [Brock 1999; Schlegel 2004]. The agar provides a solid surface that does not decay to a messy liquid as microorganisms grow on it. Agar-filled Petri dishes are now virtually ubiquitous in biology laboratories for culturing microorganisms.

- By 1890, Carl Wehmer (1858–1935) was using yeast fermentation to produce citric acid, fumaric acid, and other substances [Benninga 1990]. See Fig. 2.69.

- Franz Schardinger (Austrian, 1853–1920) used bacterial fermentation to produce acetone (1903–1904). See Fig. 2.70 for some of his publications demonstrating his methods and results.

- In 1910, Chaim Azriel Weizmann (Belarus, educated and worked in Germany and Switzerland, 1874–1952) began internationally popularizing Schardinger's methods of using bacterial fermentation to produce acetone. (Sometimes international credit was given to Weizmann for popularizing these methods, but not to Schardinger for first inventing, demonstrating, and publishing these methods.)

- In the early twentieth century, bioreactors for the continuous liquid culture of microorganisms were developed by scientists at Benkiser, Boehringer, I.G. Farben, Phrix, Röhm and Haas, and other German companies and laboratories (Figs. 2.71–2.71). For more detailed information, see pp. 2401–2404, 2412.

- In the 1940s, the use of bioreactors for the continuous liquid culture of microorganisms was internationally popularized by German-speaking refugees such as Ernst Chain (German, 1906–1979, working in the United Kingdom) and Leo Szilard (Hungarian, 1898–1964, working in the United States, p. 183)[13], and also by Allied investigators who wrote numerous reports on the German biotechnology industry (pp. 2401–2404, 2412).

- Bioreactors are now used worldwide for a wide variety of industrial-scale production of microorganisms and products derived from them.

- See Appendix A for additional examples.

N° 146. — Note sur la fermentation citrique ;
par M. Charles WEHMER.

Les fermentations acides provoquées par les champignons filamenteux ne sont connues que pour des cas isolés, et quoique le phénomène le mieux étudié de cette catégorie, la formation oxalique, puisse être de quelque intérêt, j'estime que la fermentation citrique en a davantage. En effet, d'après mes expériences et en observant les conditions les plus favorables, il se trouve que l'acide citrique est un produit de sécrétion de quelques moisissures. Ce phénomène est une fermentation dans le genre de celle provoquée par certaines bactéries qui sécrètent les acides acétique et lactique. L'acide citrique, répandu dans le règne végétal, n'a pas encore été observé comme produit de fermentation, et le nombre des acides organiques obtenus de cette façon est restreint. Les observations que j'ai recueillies dans cet ordre d'idées sont en substance les suivantes :

Si l'on abandonne des solutions sucrées, de composition déterminée, à l'action de certains champignons, ceux-ci transforment aussitôt une partie plus ou moins grande de l'hydrate de carbone en un acide qui, chimiquement, est identique à celui que renferme le jus de citron ; on l'obtient aisément sous forme cristalline. La production de cet acide citrique de fermentation n'est pas différente, dans ses traits les plus saillants, de celles par lesquelles on obtient les acides d'un autre genre ; mais les conditions jouent dans le cas particulier un rôle essentiel.

J'ai déterminé, pour le travail qui nous occupe, deux espèces de champignons, et il se trouve que nous sommes en présence d'organismes qui ont échappé à l'observation des savants, en partie, par la raison évidente de la petite dimension de leurs organes reproducteurs et, plus encore, à leur ressemblance macroscopique frappante avec les espèces ordinaires connues.

Ces moisissures apparaissent sur le terrain qui leur convient, sous forme de tissus verts, très compacts, dont on ne distingue de différence avec les espèces du penicillium que grâce au concours du microscope, différence caractérisée, d'ailleurs, par leurs caractères physiologiques. Les différences morphologiques des deux espèces similaires sont difficiles à trouver.

Je propose d'appeler ce genre nouveau de moisissures *citromycètes*, et je désigne ces deux espèces pour les distinguer par C. pfefferianus et C. glaber ; la première en l'honneur de M. le

Verfahren zur Darstellung von Fumarsäure durch Gärung von Zucker.

Die Erfindung betrifft ein Verfahren zur Darstellung von Fumarsäure durch Gärung aus Zucker.

Der Patentinhaber hat gefunden, daß man Zucker, z. B. Maltose, Dextrose und insbesondere Rohrzucker, durch Gärung mittelst des Aspergillus fumaricus bis zu 80 % in Fumarsäure überführen kann. Gleich wie bei anderen Säuregärungen wird die entstehende freie Säure durch zugesetzte Kreide oder andere Neutralisationsmittel abgestumpft. Am Schlusse wird die Fumarsäure durch eine stärkere Säure in Freiheit gesetzt. Der als Aspergillus fumaricus bezeichnete Pilz ist die Laboratoriumsrasse einer von Soja-Bohnen aus Ost-Asien stammenden Schimmelform, die in bekannter Weise gezüchtet wird. Mit Hilfe dieses Pilzes gelingt es zum Beispiel, Rohrzuckerlösungen mit hoher Ausbeute auf Fumarsäure zu vergären, so daß im Mittel 123 % des Zuckers an rohem Calciumfumarat (Maximum bis ca. 160 %) erhalten wurden. Man verfährt also zweckmäßig in der Weise, daß die durch Aufkochen steril gemachten Zuckerlösungen beliebiger Konzentration in geeigneten Gefäßen nach Zugabe eines Neutralisationsmittels, wie Kreide oder dergleichen, mit einer Reinkultur geimpft werden. Bei Verwendung von reinem Zucker sind die üblichen Pilznährstoffe zuzusetzen. Die Pilzentwicklung verläuft unter sonst günstigen Verhältnissen in wenigen Tagen. Die entstehende freie Fumarsäure löst die zugesetzte Kreide unter Gasentwicklung allmählich auf; an ihrer Stelle erscheinen alsdann derbe Krusten von kristallisiertem fumarsaurem Kalk. Nach Trennung von der Flüssigkeit wird aus ihnen durch Schwefelsäure freie kristallisierte Fumarsäure abgeschieden. Die erhältliche Fumarsäure ist in ihren Eigenschaften mit der käuflichen Säure übereinstimmend, sie sublimiert oberhalb 200° unzersetzt in feinen Nädelchen. Der Schmelzpunkt liegt beim Schmelzen in geschlossenen Röhrchen bei ca. 278°.

Beispiel:

Eine Lösung von 100 Teilen Zucker in 1 Liter Wasser wird nach Zusatz von 25 gr Kreide und den üblichen Pilznährstoffen mit einer Kultur des Fumarsäurepilzes geimpft. In 2—3 Wochen langer Gärung bei 20° scheiden sich rund 120 gr Calciumfumarat ab, aus dem durch Schwefelsäure die Fumarsäure freigemacht und durch Lösen in Alkohol und Filtrieren der Lösung vom Gips getrennt wird. Man kann auch das Kalksalz zunächst in das Bleisalz überführen und dieses durch Schwefelwasserstoff zerlegen.

PATENTANSPRUCH:

Verfahren zur Darstellung von Fumarsäure durch Gärung aus Zucker, dadurch gekennzeichnet, daß man eine Zuckerlösung mittelst Aspergillus fumaricus vergärt, die dabei entstehende freie Fumarsäure durch zugesetzte Neutralisationsmittel bindet und hierauf durch eine stärkere Säure in Freiheit setzt.

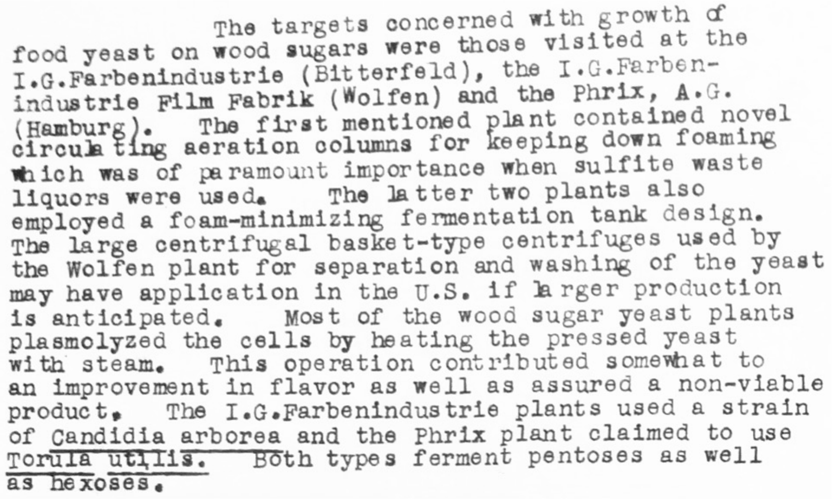
FIAT 195. ***Yeast and Nutrition Targets in Germany.***

BIOS 1776. ***Yeast and Citric Acid Production from Sugar Beet Molasses in Germany.***



The targets concerned with growth of food yeast on wood sugars were those visited at the I.G.Farbenindustrie (Bitterfeld), the I.G.Farbenindustrie Film Fabrik (Wolfen) and the Phrix, A.G. (Hamburg). The first mentioned plant contained novel circulating aeration columns for keeping down foaming which was of paramount importance when sulfite waste liquors were used. The latter two plants also employed a foam-minimizing fermentation tank design. The large centrifugal basket-type centrifuges used by the Wolfen plant for separation and washing of the yeast may have application in the U.S. if larger production is anticipated. Most of the wood sugar yeast plants plasmolyzed the cells by heating the pressed yeast with steam. This operation contributed somewhat to an improvement in flavor as well as assured a non-viable product. The I.G.Farbenindustrie plants used a strain of Candidia arborea and the Phrix plant claimed to use Torula utilis. Both types ferment pentoses as well as hexoses.

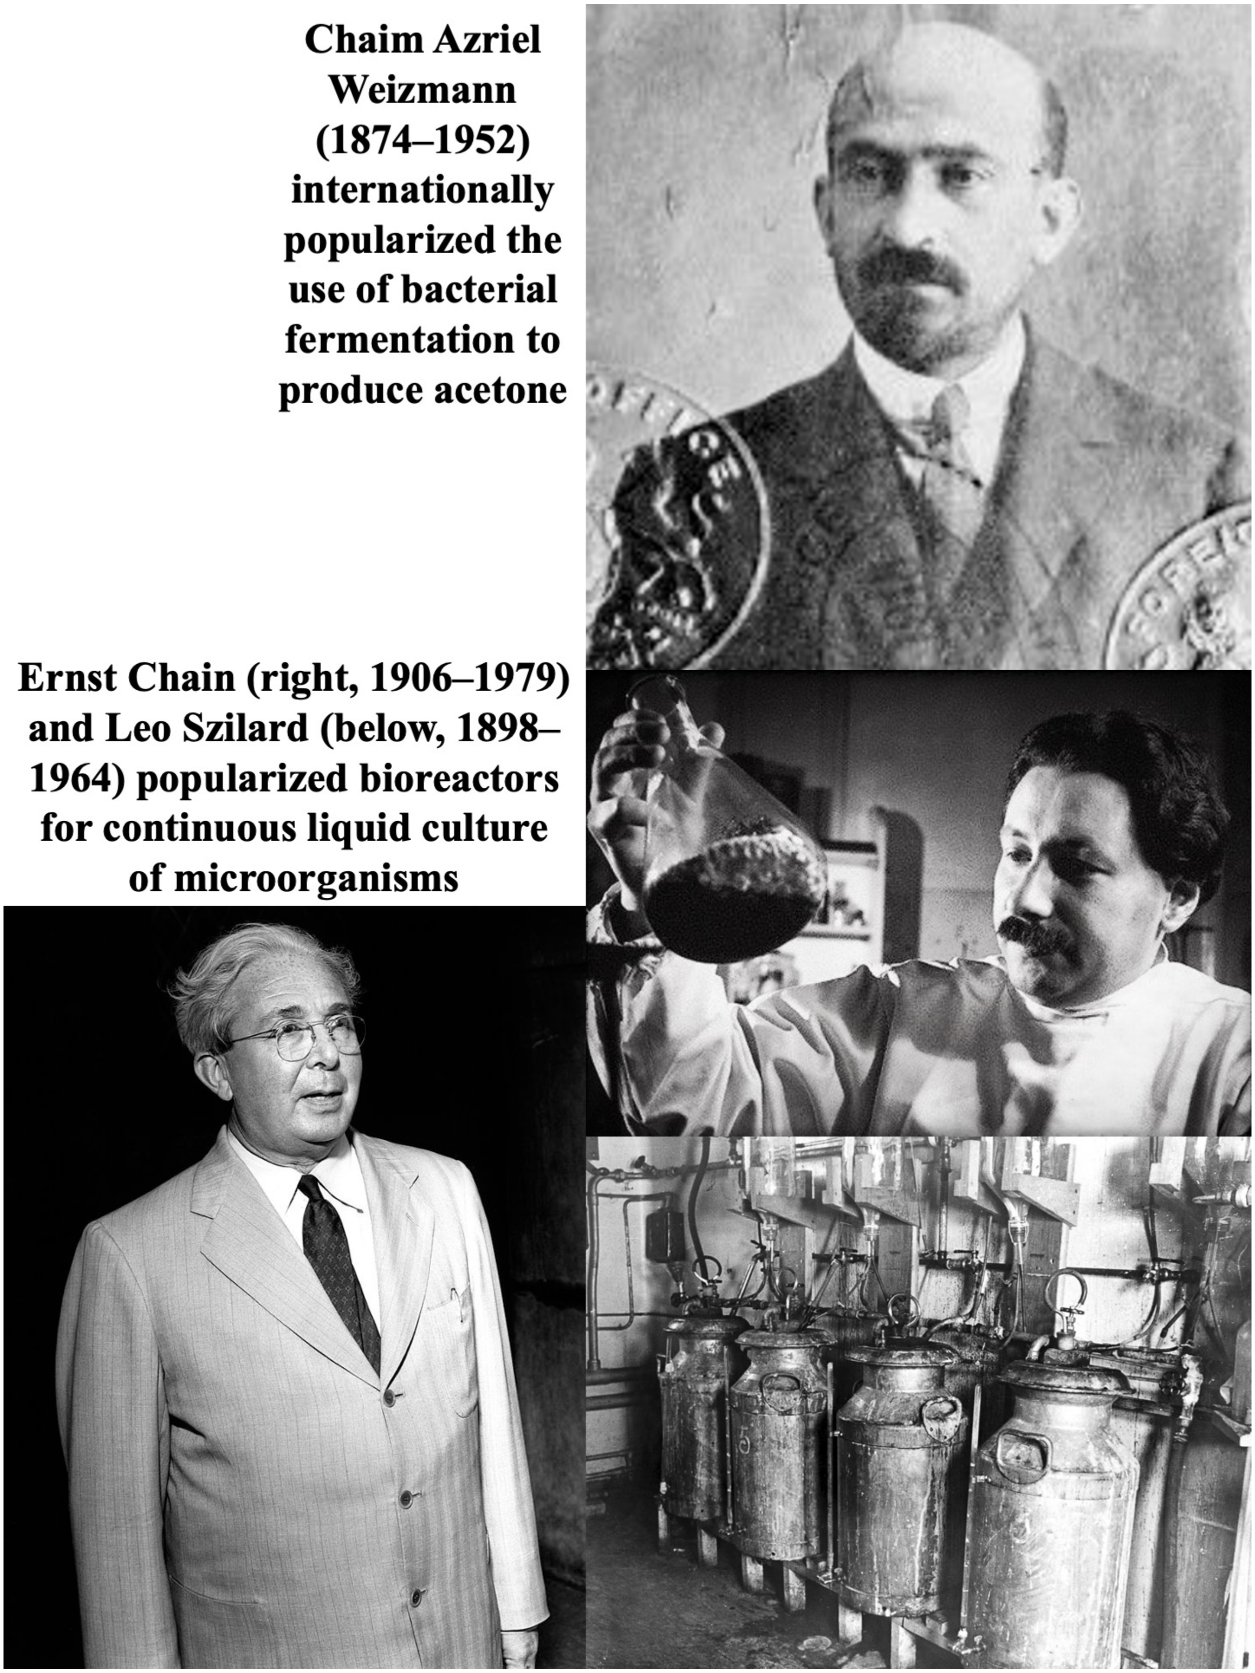
Bioreactors for continuous liquid culture

FIAT 910. *Production of Pharmaceutical and Industrial Enzymes in Southern Germany*

Figure 2.72: In the early twentieth century, bioreactors for the continuous liquid culture of microorganisms were developed by scientists at several German companies. These methods were later popularized internationally by Allied investigators who wrote numerous reports on the German biotechnology industry. [BIOS 236; FIAT 910]



Chaim Azriel Weizmann (1874–1952) internationally popularized the use of bacterial fermentation to produce acetone

Ernst Chain (right, 1906–1979) and Leo Szilard (below, 1898–1964) popularized bioreactors for continuous liquid culture of microorganisms

Figure 2.73: In 1910, Chaim Azriel Weizmann began internationally popularizing Schardinger's methods of using bacterial fermentation to produce acetone. In the 1940s, Ernst Chain and Leo Szilard internationally popularized bioreactors for continuous liquid culture of microorganisms.

Julius Wagner-Jauregg (Austrian, 1857–1940) showed that some bacterial infections could be successfully treated by infecting the patient with malaria parasites to induce a high fever, then later curing the malaria with quinine. This method was called pyrotherapy (Fig. 2.74). He won the Nobel Prize in Physiology or Medicine in 1927, although his method became obsolete with the development of antibiotics in the following years. The Royal Swedish Academy of Sciences noted [https://www.nobelprize.org/prizes/medicine/1927/wagner-jauregg/facts/]:

> General paralysis is a stage in syphilis when the brain and psyche are attacked and the patient ends up in a lethargic and paralytic state that can end in death. As far back as antiquity, people noted that mental illnesses could be ameliorated by fevers. In 1917 Julius Wagner-Jauregg exposed patients to malaria-infected blood and could in this way cure or alleviate general paralysis. The malaria was of a type that was comparatively innocuous, and consequently the patient's health could be improved.

Scientists from the German-speaking world played leading roles in developing antibiotics to treat or prevent bacterial infections.[14] The process of discovering and developing suitable antibiotic molecules was challenging because they needed to be effective at killing bacterial cells yet not kill human cells, and they also had to be produced and purified with sufficiently quantity and quality. Some of the major scientists are shown in Figs. 2.75–2.78.

Paul Ehrlich (German, 1854–1915) discovered Salvarsan in 1909 and successfully used it to treat syphilis, caused by the sexually transmitted bacterium *Treponema pallidum* [Hüntelmann 2011]. He won the Nobel Prize in Physiology or Medicine in 1908 for his earlier work on immunology (see p. 222).

Gerhard Domagk (German, 1895–1964) discovered and demonstrated sulfa antibiotics, the first broad-spectrum antibiotics, in 1932 [Domagk 1935; Grundmann 2004; Hager 2006]. In 1939, he won the Nobel Prize in Physiology or Medicine for that work.

Even by the standard of other Nobel Prize awards, Professor N. Svartz, member of the Royal Caroline Institute, gave extremely high praise for Domagk's discoveries [https://www.nobelprize.org/prizes/medicine/1939/ceremony-speech/]:

> During the investigations conducted by Domagk and his co-workers 4-sulphonamide-2', 4'-diaminoazobenzene hydrochloride, among other substances, was tested. This preparation was subsequently named Prontosil. The earliest published experiments with Prontosil were begun in December 1932. The lethal dose, for mice, of a certain strain of haemolytic streptococci, which had been isolated from a patient suffering from blood poisoning, had previously been determined. A number of mice were injected with 10 times the lethal dose of this bacterial strain, and approximately half of them were given a specific quantity of Prontosil 1 1/2 hours after being infected.

[14] Bud 2006; Ronald Clark 1985; Domagk 1935; Gradmann and Simon 2010; Grundmann 2004; Hager 2006; Hüntelmann 2011; Jahn 2004; Junker 2004; Koesling and Schülke 2010; Kohler 2008; Lax 2004; Magner 2002; Possehl 1989; Raviña and Kubinyi 2011; Schneider 1972; von Schwerin 2013; Sneader 2005; Weatherall 1991.

> On 24th December, 1932, it was found that in an experiment begun on 20th December, 1932, all the controls had died, whereas all the mice which had been given Prontosil were alive and well. This was the basis of the discovery which was destined to bring undreamed-of advances in chemotherapy. [...]
>
> In addition, brilliant results have been obtained with certain infections not due to streptococci, namely gonorrhoea and epidemic meningitis, and, as already mentioned, an effect has also been shown with staphylococcal infections.
>
> This preparation, which is so effective against various coccal infections, has also been used with success in the case of certain infections due to bacilli, e.g. cold infections. Sulphonamide is therefore now the best known remedy against infections of the urinary passages due to colon bacilli. Preparations of this group are also effective against undulant fever as well as, to a lesser extent, other bacillary infections which will not be enumerated here. [...]
>
> Professor Gerhard Domagk was awarded the 1939 Nobel Prize for Physiology or Medicine for the discovery of the antibacterial effects of Protonsil. Protonsil was the first of the so-called sulpha preparations, which have proved to represent one of the greatest therapeutic advances in the history of medicine.

Ernst Chain (German, 1906–1979) purified penicillin, another broad-spectrum antibiotic, in 1940, making it available for human use. He won the Nobel Prize in Physiology or Medicine in 1945 for that work [Ronald Clark 1985; Lax 2004]. Alexander Fleming (Scottish, 1881–1955) shared in that Nobel Prize; he is famous for having earlier discovered penicillin-producing fungal cells, but he had been unable to purify the penicillin or to scale up its production—both problems were solved by Chain. Howard Florey (Australian, 1898–1968) also shared in the Prize; he appears to have focused largely on testing penicillin in animals and humans, leaving most of the actual production and purification of penicillin to Chain. The Royal Caroline Institute noted [https://www.nobelprize.org/prizes/medicine/1945/chain/facts/]:

> After Alexander Fleming's 1928 discovery that a certain mold produced a substance called penicillin that inhibited the growth of bacteria, it was not a major leap to think that penicillin could be used as a pharmaceutical. However, the substance proved to be unstable and difficult to produce in pure form. Ernst Boris Chain, Howard Florey, and their colleagues succeeded in systematically producing a pure form of penicillin at the beginning of the 1940s and in investigating its properties in more detail. Additional efforts led to a pharmaceutical that could be produced in larger quantities.

Richard Kuhn (Austrian, 1900–1967) produced and tested synthetic antibiotics during World War II, identifying a promising antibiotic (dubbed "3065") and paving the way for later industrial parallel synthesis, screening, and structure-activity relationship testing to identify and optimize new drug molecules [CIOS ER 1, 75, 159]. Kuhn won the Nobel Prize in chemistry in 1938 for unrelated research on vitamins (p. 347).

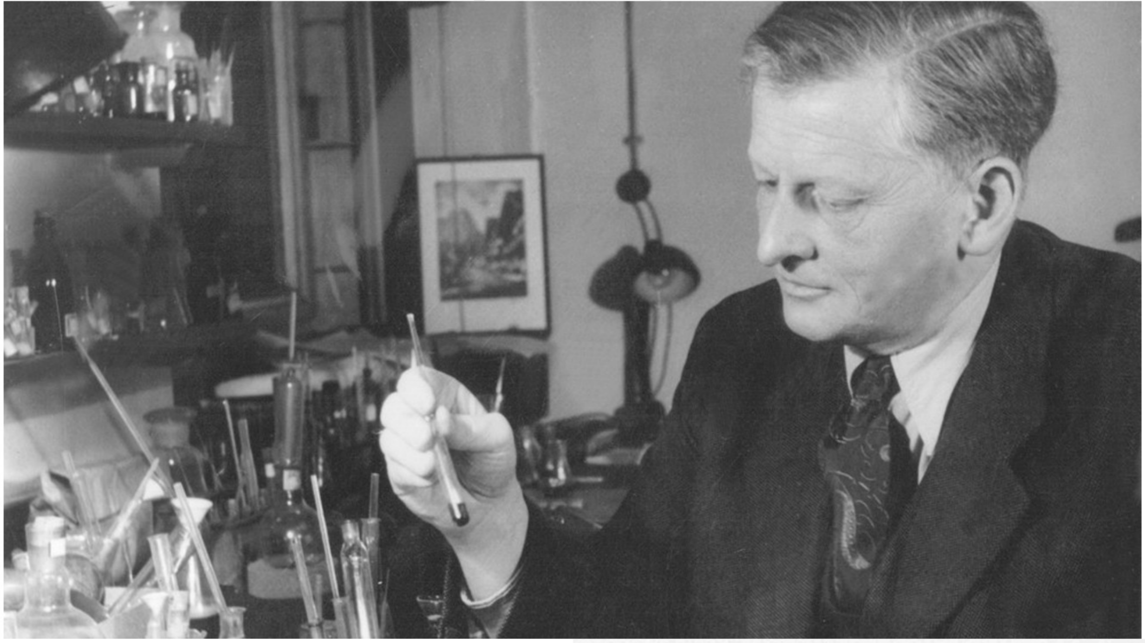
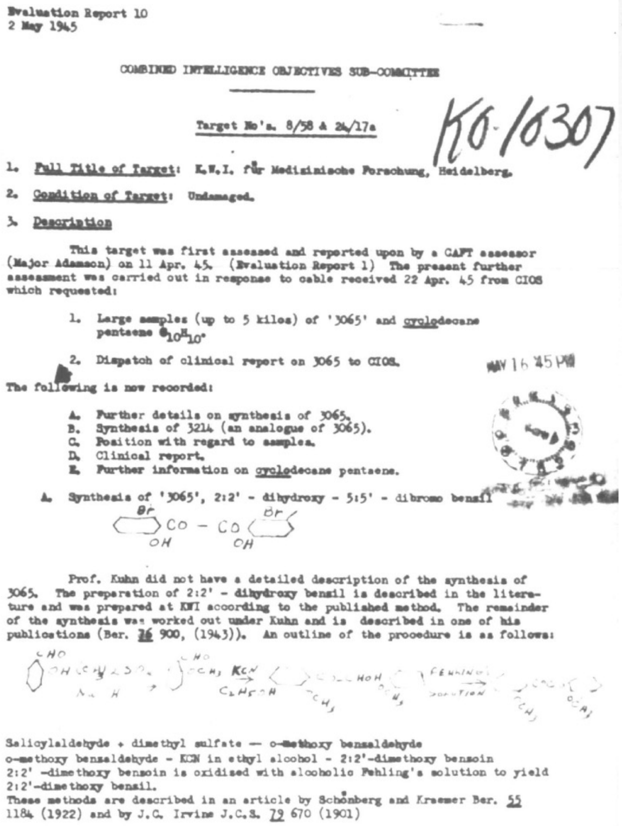
Richard Kuhn (1900–1967) produced and tested synthetic antibiotics such as "3065" during WWII, using massively parallel chemical synthesis and testing to carry out very modern methods of structure-activity relationship (SAR) optimization of the molecules.





Evaluation Report 10
2 May 1945

COMBINED INTELLIGENCE OBJECTIVES SUB-COMMITTEE

Target No's. 8/58 & 24/17a

KO-10307

1. Full Title of Target: K.W.I. für Medizinische Forschung, Heidelberg.

2. Condition of Target: Undamaged.

3. Description

This target was first assessed and reported upon by a CAFT assessor (Major Adamson) on 11 Apr. 45. (Evaluation Report 1) The present further assessment was carried out in response to cable received 22 Apr. 45 from CIOS which requested:

1. Large samples (up to 5 kilos) of '3065' and cyclodecane pentaene $C_{10}H_{10}$.
2. Dispatch of clinical report on 3065 to CIOS.

MAY 16 '45 PM

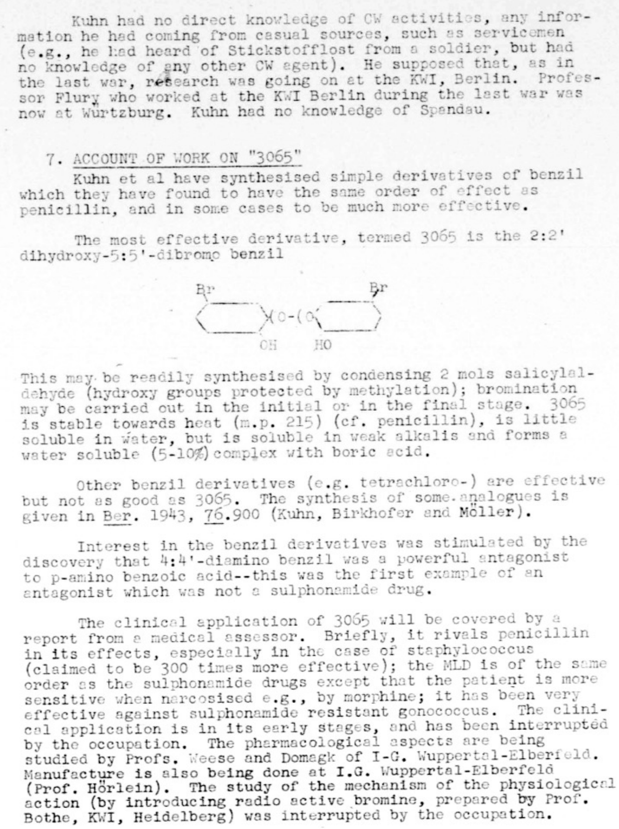
The following is now recorded:

A. Further details on synthesis of 3065.
B. Synthesis of 3214 (an analogue of 3065).
C. Position with regard to samples.
D. Clinical report.
E. Further information on cyclodecane pentaene.

A. Synthesis of '3065', 2:2' - dihydroxy - 5:5' - dibromo benzil

Prof. Kuhn did not have a detailed description of the synthesis of 3065. The preparation of 2:2' - dihydroxy benzil is described in the literature and was prepared at KWI according to the published method. The remainder of the synthesis was worked out under Kuhn and is described in one of his publications (Ber. 76 900, (1943)). An outline of the procedure is as follows:

Salicylaldehyde + dimethyl sulfate — o-methoxy benzaldehyde
o-methoxy benzaldehyde - KCN in ethyl alcohol - 2:2'-dimethoxy benzoin
2:2' -dimethoxy benzoin is oxidised with alcoholic Fehling's solution to yield 2:2'-dimethoxy benzil.
These methods are described in an article by Schönberg and Kraemer Ber. 55 1184 (1922) and by J.C. Irvine J.C.S. 79 670 (1901)



Kuhn had no direct knowledge of CW activities, any information he had coming from casual sources, such as servicemen (e.g., he had heard of Stickstofflost from a soldier, but had no knowledge of any other CW agent). He supposed that, as in the last war, research was going on at the KWI, Berlin. Professor Flury who worked at the KWI Berlin during the last war was now at Würtzburg. Kuhn had no knowledge of Spandau.

7. ACCOUNT OF WORK ON "3065"

Kuhn et al have synthesised simple derivatives of benzil which they have found to have the same order of effect as penicillin, and in some cases to be much more effective.

The most effective derivative, termed 3065 is the 2:2' dihydroxy-5:5'-dibromo benzil

This may be readily synthesised by condensing 2 mols salicylaldehyde (hydroxy groups protected by methylation); bromination may be carried out in the initial or in the final stage. 3065 is stable towards heat (m.p. 215) (cf. penicillin), is little soluble in water, but is soluble in weak alkalis and forms a water soluble (5-10%) complex with boric acid.

Other benzil derivatives (e.g. tetrachloro-) are effective but not as good as 3065. The synthesis of some analogues is given in Ber. 1943, 76.900 (Kuhn, Birkhofer and Möller).

Interest in the benzil derivatives was stimulated by the discovery that 4:4'-diamino benzil was a powerful antagonist to p-amino benzoic acid--this was the first example of an antagonist which was not a sulphonamide drug.

The clinical application of 3065 will be covered by a report from a medical assessor. Briefly, it rivals penicillin in its effects, especially in the case of staphylococcus (claimed to be 300 times more effective); the MLD is of the same order as the sulphonamide drugs except that the patient is more sensitive when narcosised e.g., by morphine; it has been very effective against sulphonamide resistant gonococcus. The clinical application is in its early stages, and has been interrupted by the occupation. The pharmacological aspects are being studied by Profs. Weese and Domagk of I-G. Wuppertal-Elberfeld. Manufacture is also being done at I.G. Wuppertal-Elberfeld (Prof. Hörlein). The study of the mechanism of the physiological action (by introducing radio active bromine, prepared by Prof. Bothe, KWI, Heidelberg) was interrupted by the occupation.

Figure 2.78: Richard Kuhn produced and tested synthetic antibiotics such as "3065" during WWII, using massively parallel chemical synthesis and testing to carry out very modern methods of structure-activity relationship (SAR) optimization of the molecules.

2.2.2 Viruses

As shown in Fig. 2.79, viruses usually consist of just a few genes, packaged into a capsid made of proteins. The majority of viruses use RNA to encode their genome, although some viruses use DNA just as cells do. Some viruses wrap themselves in a protective envelope membrane to try to hide from their host's immune system, and some do not.

Viruses can range in size from smaller than 20 nm (for parvoviruses) to larger than 350 nm (for smallpox), with ∼50 nm as a typical average size. That means that virtually all viruses are too small to be seen with even the best possible light microscope, and therefore early virology researchers had to content themselves by proving that samples contained something that was infectious but too small to see. It also means that when German-speaking scientists invented electron microscopes, which could see things as small as viruses, that was a major step forward for virology.

Figure 2.80 shows how a typical virus replicates. Viruses do not have the machinery to replicate themselves, so they must invade a suitable host cell (human, animal, plant, or even bacterial cell, depending on the particular type of virus) and force the infected host cell to produce more copies of the virus. The small number of viral genes tell the host cell what to do and block the host cell from fighting off the infection. Most RNA viruses replicate outside the cellular nucleus as shown in the figure, and most DNA viruses replicate inside the nucleus.

German-speaking scientists made a large number of important discoveries in the early history of virology.[15] As with bacteriology, the most notable contributions to virology outside the German-speaking world came from Louis Pasteur, whose development of the rabies vaccine was a scientific tour de force that was probably decades ahead of its time.

Peter Plett (German states, 1766–1823) developed and successfully demonstrated a cowpox-based vaccine for smallpox virus beginning in the late 1780s, and first reported his results in 1790. Edward Jenner (English, 1749–1823) rediscovered the same thing several years later, and published his first results in 1798. Yet Jenner became famous as the discoverer of smallpox vaccine, and Plett has been virtually forgotten [Plett 2006]. See Fig. 2.81.

Advances in knowledge about the actual nature of viruses required specific viruses that could be tested in a variety of ways under laboratory conditions, and that were important enough to justify the expense of doing so. The German-speaking world identified and began unlocking the mysteries of two such model viruses roughly in parallel: tobacco mosaic virus (TMV), which infects tobacco plants (considered a valuable crop), and foot-and-mouth disease virus (FMDV), which infects cattle, pigs, sheep, goats, and deer.

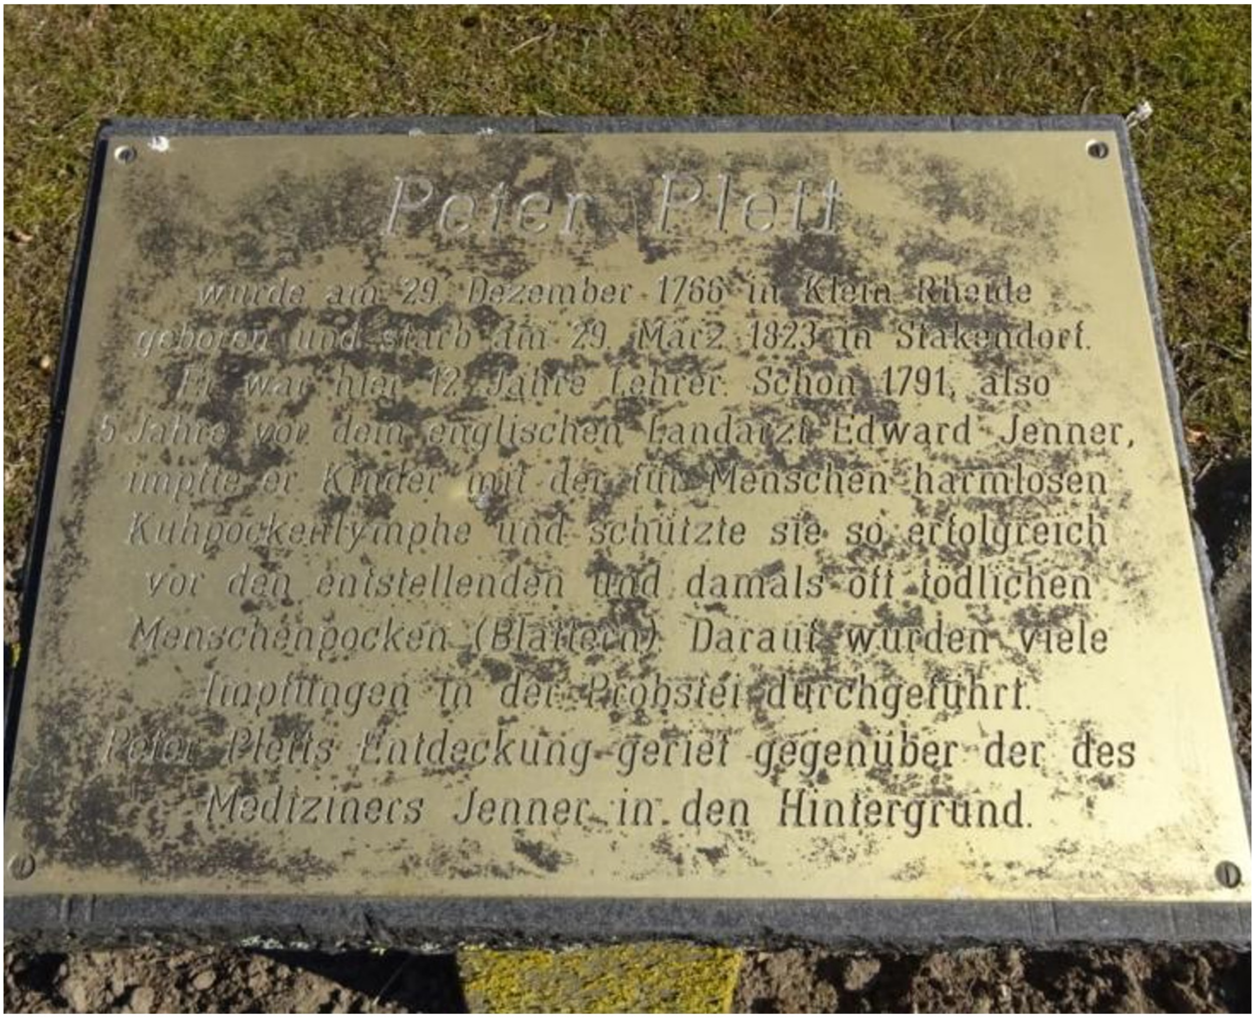
Peter Plett (1766–1823) developed and successfully demonstrated a cowpox-based vaccine for smallpox virus beginning in the late 1780s, roughly a decade before Edward Jenner.



Peter Plett

wurde am 29. Dezember 1766 in Klein Rheide
geboren und starb am 29. März 1823 in Stakendorf.
Er war hier 12 Jahre Lehrer. Schon 1791, also
5 Jahre vor dem englischen Landarzt Edward Jenner,
impfte er Kinder mit der für Menschen harmlosen
Kuhpockenlymphe und schützte sie so erfolgreich
vor den entstellenden und damals oft tödlichen
Menschenpocken (Blattern). Darauf wurden viele
Impfungen in der Probstei durchgeführt.
Peter Pletts Entdeckung geriet gegenüber der des
Mediziners Jenner in den Hintergrund.

Figure 2.81: Peter Plett (1766–1823) developed and successfully demonstrated a cowpox-based vaccine for smallpox virus beginning in the late 1780s, roughly a decade before Edward Jenner.

As shown in Fig. 2.82, scientists who studied tobacco mosaic virus included:

- Adolf Eduard Mayer (German, 1843–1942) discovered the tobacco mosaic virus (TMV), a virus that infects tobacco plants, in 1886. He found that the pathogen was too small to be seen with a microscope (unlike bacteria) and was uncertain about its exact nature.

- In a series of experiments in the 1890s, Martinus Beijerinck (Dutch, 1851–1931) demonstrated that TMV was not a bacterium–it was much smaller, could not be cultured in nutrient medium, and only replicated in tobacco plants. He coined the term "virus" to describe this type of pathogen.

- Gerhard Schramm (1910–1969) conducted a series of remarkably advanced experiments in the late 1930s and early 1940s to investigate the molecular composition and functions of TMV. He demonstrated TMV's nucleic acid components could be separated from its protein components, and that the nucleic acid (RNA) by itself was infectious in plants and therefore carried genetic information. He also showed that he could make individual mutations in the nucleic acid, leading to corresponding changes in the proteins and viruses that were produced in infected plants—thus nucleic acids contained genes that encoded protein sequences. He also showed that the proteins forming the viral structure around the nucleic acid were all identical, suggesting how they assembled into symmetrical geometric structures. His experiments might have gone even further if he had not been hampered by shortages and restrictions in wartime Germany.[16]

- Heinz Fränkel-Conrat (German, 1910–1999) independently replicated and extended many of Schramm's experiments on the molecular biology of TMV in the United States after the war.

Figure 2.82: Scientists who studied tobacco mosaic virus included Adolf Eduard Mayer, Martinus Beijerinck, Gerhard Schramm, and Heinz Fränkel-Conrat.

Scientists who studied foot-and-mouth disease virus (FMDV) included:[17]

- Friedrich Löffler (German, 1852–1915, Fig. 2.83) and Paul Frosch (German, 1860–1928, Fig. 2.83), who had both worked with Robert Koch, discovered foot-and-mouth disease virus (FMDV) in 1897, demonstrating that the pathogen was not a bacterium. Löffler went on to help create what became known as the Friedrich Löffler Institute on Riems island on the Baltic coast of Germany, where experiments on FMDV and other animal viruses could be conducted in isolation.

- Carl Hecker (German?, 1868–1910, Fig. 2.83) immediately developed the first FMDV animal models (smaller animals that could be infected with the virus and therefore used to test potential treatments) and anti-FMDV immune serum during the period 1897–1899.

- Otto Waldmann (German, 1885–1955, Fig. 2.84) was the head of the FLI during the period 1919–1948. In addition to his administrative duties, he was very active scientifically. Working with Julius Pape (German?, 18??–19??), he developed a guinea pig model of FMDV in 1920. Together with Gottfried Pyl (19??–19??) and Carl Köbe (19??–19??), he developed a highly effective FMDV vaccine in 1938.

- Some other especially noteworthy scientists working on FMDV at FLI were Erich Traub (German, 1906–1985, Fig. 2.84), who was Waldmann's deputy for several years before becoming a consultant to U.S. animal labs after the war, and Friedrich Hecke (German?, 18??–19??), who developed a remarkably early and advanced tissue culture model of FMDV infection in 1930. In 1943, FLI scientists also developed a complement-binding immunoassay that could distinguish between different FMDV strains within less than one day.

German discoveries regarding FMDV were transferred to and utilized by the rest of the world. See for example FIAT 900, *The Waldmann Vaccine (Against Aphthous Stomatitis)*.

stanzen im Blute, das letztere dessen ungeachtet jeden Augenblick in dieser Periode der Krankheit noch lebende Spirochäten enthalten kann.

Die Untersuchungen der letzten Zeit über die Verteilung von spezifischen, agglutinierenden und antitoxischen Substanzen im Organismus beweisen zur Evidenz, daß der Gehalt dieser Stoffe im Blute selbst, in flüssigen physiologischen und pathologischen Exkreten, sowie in inneren Organen und Geweben lange nicht überall quantitativ gleichmäßig verteilt ist. Solche Untersuchungen liegen vor von Tizzoni und Cattani[1]) über die vaccinierenden Substanzen im Organismus der gegen Tetanus immunisierten Tiere, von Widal, Achard und Bensaude[2]) über die agglutinierenden, und von Prof. Metschnikoff[3]) über die antitoxischen Stoffe. Diesen Untersuchungen kann ich die meinigen über die Verteilung der baktericiden Substanzen im Organismus anreihen und dadurch den scheinbaren Widerspruch entkräften. (Fortsetzung folgt.)

Nachdruck verboten.

Berichte der Kommission zur Erforschung der Maul- und Klauenseuche bei dem Institut für Infektionskrankheiten in Berlin.

Erstattet an den Kultusminister

von

Geh. Med.-Rat Prof. Dr. **Loeffler** und Prof. Dr. **Frosch.**

Berlin, den 17. April 1897.

Euerer Excellenz beehrt sich die unterzeichnete Kommission nachstehend das Ergebnis der bisher von derselben angestellten Untersuchungen über die Maul- und Klauenseuche ganz gehorsamst zu berichten.

1. Untersuchungen über die Aetiologie der Seuche.

Dank den telegraphischen Mitteilungen über frische Ausbrüche von Maul- und Klauenseuche, welche gemäß Euerer Excellenz hoher Verfügung seitens zahlreicher Lokalbehörden an das Institut für Infektionskrankheiten gelangt sind, war es uns möglich, reichliches frisches Material für diese Untersuchung zu beschaffen. Es wurden für diesen Zweck solche Orte ausgewählt, welche ein Zurückkehren am selben Tage und sofortige Verarbeitung des frisch entnommenen Materials gestatteten. Die Kommission hat derartige Reisen unternommen zweimal nach Prenzlau, nach Johanneswunsch bei Zantoch a. W. und zweimal nach Golzow bei Britz; an der letzten Fahrt

„Der Siegespreis doch einem Thierarzt!“

Bemerkungen zu dem „Summarischen Bericht über die Ergebnisse der Untersuchungen der Commission zur Erforschung der Maul- und Klauenseuche“.

Von

C. Hecker-Ermsleben a. Harz,

pract. Thierarzt.

Mit lebhaftem Interesse wurde wohl von allen Fachgenossen der Summarische Bericht über die Ergebnisse der Untersuchungen der Commission zur Erforschung der Maul- und Klauenseuche gelesen. Von keinem Thierarzte vielleicht mit so freudigen Gefühlen wie von mir! Sind doch die Ergebnisse der Versuche der Herren Professoren Dr. Loeffler und Dr. Frosch gleichsam eine amtliche Bestätigung **meiner** Erfolge! Ohne diese sicher mühevoll errungenen Ergebnisse der Untersuchungen genannter Herren irgendwie zu schmälern, möchte ich jedoch nicht ohne Weiteres „den Siegespreis bei dieser zur Zeit wichtigsten Thierkrankheit einem Mediciner“, wie die Anmerkung der Redaction in voriger Nummer der B. T. W. sagt, zuerkennen. Denn über die Priorität der thatsächlich ausgeführten Immunisirungsversuche kann, wie das Folgende ergeben wird, kein Zweifel aufkommen.

Die zuerst errungenen Erfolge, sie sollen der Thierheilkunde bleiben.

Als an die Einsetzung einer Commission noch garnicht gedacht wurde, hatte ich nachweislich schon positive, practische Vorarbeiten für mein Verfahren aufzuweisen. Als sich die Commission wahrscheinlich noch mit theoretischen Erwägungen beschäftigt haben wird, konnte ich schon durch eine grosse Zahl practisch ausgeführter Versuche den Beweis liefern, dass meine Immunisirungsversuche und das darauf begründete Bekämpfungsverfahren nicht allein wissenschaftlich richtig, sondern auch in der Praxis leicht verwerthbar war.

Schon im November vorigen Jahres, ferner im März d. J. stellte ich bei Seucheausbrüchen auf hiesigen Gütern Schutzserum aus dem Blute immunisirter Rinder dar. — Ich hätte meine Versuche im April schon durch eine sogenannte „Vorläufige Mittheilung“ schützen können, hielt aber solches Verfahren in der Wissenschaft für Unfug.

Doch einige Beweise für das Behauptete!

I. Schon zu Anfang dieses Jahres — es war Ende Februar oder Anfang März — schrieb ich an die Landwirthschaftskammer für die Provinz Sachsen fast wörtlich*) in einem Bericht über meine Resolution zur Bekämpfung der Schweineseuchen**), wie folgt:

„. . . . Anders läge die Prophylaxe bei der Schweineseuche: Hier kann hoffentlich auch die Bacteriologie helfen! Zunächst wären Impfversuche mit geschwächten, mitigirten Schweineseuchecoccenculturen auszuführen, hieraus dann Serumpräparate herzustellen, von Thieren, welche mit qu. Seuche inficirt und gesundet sind (nicht nur von Schweinen! Versuche bei grösseren Hausthieren).

Der Thierarzt der Praxis ist leider nur selten in der glücklichen Lage, eingehende wissenschaftliche Untersuchungen und Versuche zu machen, denn einerseits fehlen dem Practiker meist die Zeit, andererseits die Geldmittel, wohingegen den Laboratorien und Instituten der grossen Städte die Gelegenheit zu Versuchen und Beobachtungen, wie sie nur die Praxis bietet, entgeht. Diese Factoren lassen es meines Erachtens nach erklärlich erscheinen, dass auch die Untersuchungen über Maul- und Klauenseuche bisher so wenig erfolgreich sind! Die bacteriologischen Versuche erstrecken sich meines Wissens fast nur auf die Krankheit der Wiederkäuer. Das Untersuchungsfeld ist aber bei Rindern mit ihren unendlichen Mengen von Mikroorganismen in Maul, Magen, Klauen u. s. w. gar nicht bacteriologisch rein zu erhalten. Doch auch bei Gänsen, Rebhühnern, Katzen u. s. w. ist Maul- und Klauenseuche beobachtet worden. Diese Thiere sind wegen der Billigkeit, Regulirung der Fütterung, Kleinheit und Reinhaltung des Untersuchungsfeldes die geeignetsten Versuchsobjecte — vorausgesetzt, dass die Inficirung bei diesen Thieren gelingt! Auch Versuche am Schweine sind bedeutend leichter auszuführen als am Rinde.

Da die von der Maul- und Klauenseuche befallenen Wiederkäuer für gewisse Zeit immun sind, wird auch bei ihnen das Blutserum die Kraft der Immunität und des Immunisirens haben! Deshalb zunächst Versuche mit Serum (!), welches bei der stets vorhandenen

---

*) Obiges ist dem Concept entnommen; es kann sich nur um Abweichungen handeln, wie sie die Reinschrift erklärlich macht.

Viral infections
Foot-and-mouth disease virus (discovered 1897)
Otto Waldmann (1885–1955)
Erich Traub (1906–1985)

Figure 2.84: Scientists who studied foot-and-mouth disease virus included Otto Waldmann and Erich Traub.

Figure 2.85 shows an electron microscope image of poliovirus, the cause of polio. Poliovirus was discovered in 1908 by Karl Landsteiner (Austrian, 1868–1943) and Erwin Popper (Austrian, 1879–1955). Marguerite Vogt (German, 1913–2007) developed methods to grow poliovirus and polyoma virus in tissue culture, and also pursued cancer research.

As shown in Fig. 2.86, some other German-speaking scientists who made important early contributions to virology included:

- Max Delbrück (German, 1906–1981) did important early work on bacteriophages, viruses that infect bacteria. He won the Nobel Prize in Physiology or Medicine in 1969. Professor Sven Gad of the Royal Caroline Institute emphasized the importance of the discoveries of Delbrück and his coworkers [https://www.nobelprize.org/prizes/medicine/1969/ceremony-speech/]:

  > The honour in the first place goes to Delbrück who transformed bacteriophage research from vague empiricism to an exact science. He analyzed and defined the conditions for precise measurement of the biological effects. Together with Luria he elaborated the quantitative methods and established the statistical criteria for evaluation which made the subsequent penetrating studies possible. [...]
  >
  > The research proceeded along the lines Delbrück had set for a little more than ten years. During this period the bacteriophage life cycle was mapped out in detail. The various phases of the replication process were dissected and studied separately. [...]
  >
  > Their discoveries have also had great importance for the geneticists. It is mainly through studies of bacteriophages that the mechanisms of the genetic regulation of the vital processes have been revealed.
  >
  > Last but not least, bacteriophage research has given us the better insight in the nature of viruses which is necessary for the understanding and combat of virus diseases of higher beings. A long time has passed since the discoveries were made. However, their general biological and medical importance was only gradually recognized and only in later years has the wide range of their applicability become fully evident.

- Eugen Haagen (German, 1898–1972) was an expert on a wide variety of viral infections and wrote a handbook on viruses, *Viruskrankheiten des Menschen*, that became a standard for many years.

- Emil Pfeiffer (German, 1846–1921) was the first scientist to study what later came to be named the Epstein-Barr virus—decades before Michael Epstein and Yvonne Barr. The disease caused by the virus, infectious mononucleosis, is sometimes called Pfeiffer's disease.

- Helmut Ruska (German, 1908–1973) developed electron microscopy methods of viewing viruses, since viruses are too small to be seen by ordinary light microscopes.[18]

2.2.3 Prions

Prions are just rogue proteins and not real live microorganisms, but they can spread from one animal or human host to another and kill their hosts, so they are usually classified as part of microbiology. The normal, healthy form and the pathogenic form of a prion protein (PrP) have the same amino acid sequence as each other, but they are folded up differently, as shown in Fig. 2.87 (top). Figure 2.87 (bottom) illustrates how pathogenic prions can recruit initially healthy PrP proteins to convert them into more prions. Pathogenic prions, shown in red, tend to accumulate to form large clumps, called fibrils or plaques. Some pathogenic prions can break off from the clumps and bind to healthy prion proteins (green) normally found in the host animal or person. The pathogenic prions refold the initially healthy prion proteins into the pathogenic shape, thus gaining more converts for their cause and multiplying exponentially. If even a small number of pathogenic prions are introduced into a healthy animal or human host (for example, if the new host consumes prion-containing meat from a previous infected host), over time they can convert most of the host's prions into the pathogenic form. Because of their unique folded structure, pathogenic prions are able to survive everything from cooking of meat to lying on the ground exposed to the elements for years.

The best-known prions are formed from a protein commonly found in neurons, so when they become pathogenic, they slowly make brain tissue look like Swiss cheese, killing brain cells and leaving only holes where the cells used to be, as shown in Fig. 2.88 (top). Such prion infections are called bovine spongiform encephalopathy or mad cow disease in cattle, chronic wasting disease in deer and elk, scrapie in sheep and goats, and Creutzfeldt-Jakob disease or Kuru in humans, although they can be transmitted from one species to another.

Prion infections were discovered and studied by (Fig. 2.88):

- Hans Gerhard Creutzfeldt (German, 1885–1964), who along with Jakob identified human cases of the disease in 1920.

- Alfons Maria Jakob (German, 1884–1931), who along with Creutzfeldt diagnosed human cases of the disease in 1920.

- Friedrich Meggendorfer (German, 1880–1953), who identified an inherited familial form of Creutzfeldt-Jakob disease in 1930.

Figure 2.88: Hans Gerhard Creutzfeldt, Alfons Maria Jakob, and Friedrich Meggendorfer discovered prion infections, which tend to kill brain cells and leave lots of holes in brain tissue.

2.2.4 Fungi

As shown in Fig. 2.89, fungal cells look very similar to plant cells, but are smaller and without chloroplasts. Animal, plant, and fungal cell membranes contain different types of sterols. Plant and fungal cells both have cell walls, but of different composition. There are many nonpathogenic species of fungi that live in the environment, but also some pathogenic ones that can infect humans, animals, or plants.

Scientists from the German-speaking world made many important discoveries regarding fungal infections; Fig. 2.90 shows some examples.

Johann Schönlein (German states, 1793–1864) discovered human infections by the pathogenic fungus *Trichophyton*. *Trichophyton* and similar fungal species cause fungal skin (tinea) infections, including nail infections, scalp infections, athlete's foot, jock itch, and ringworm on the body. They secrete a keritinase enzyme that breaks down the keratin structural protein in skin, nails, and hair, then live off the resulting nutrients.

Abraham Buschke (German, 1868–1943) and Otto Busse (German, 1867–1922) discovered infections by *Cryptococcus*. *Cryptococcus* species take the form of yeast both inside and outside humans; like some bacteria, they are coated with a protective polysaccharide layer. If inhaled, they cause a mild lung infection and then head for the central nervous system, where they can cause a potentially fatal fungal mengingoencephalitis.

Heinrich Anton de Bary (German, 1831–1888) discovered fungal infections in plants.

2.2.5 Protozoa

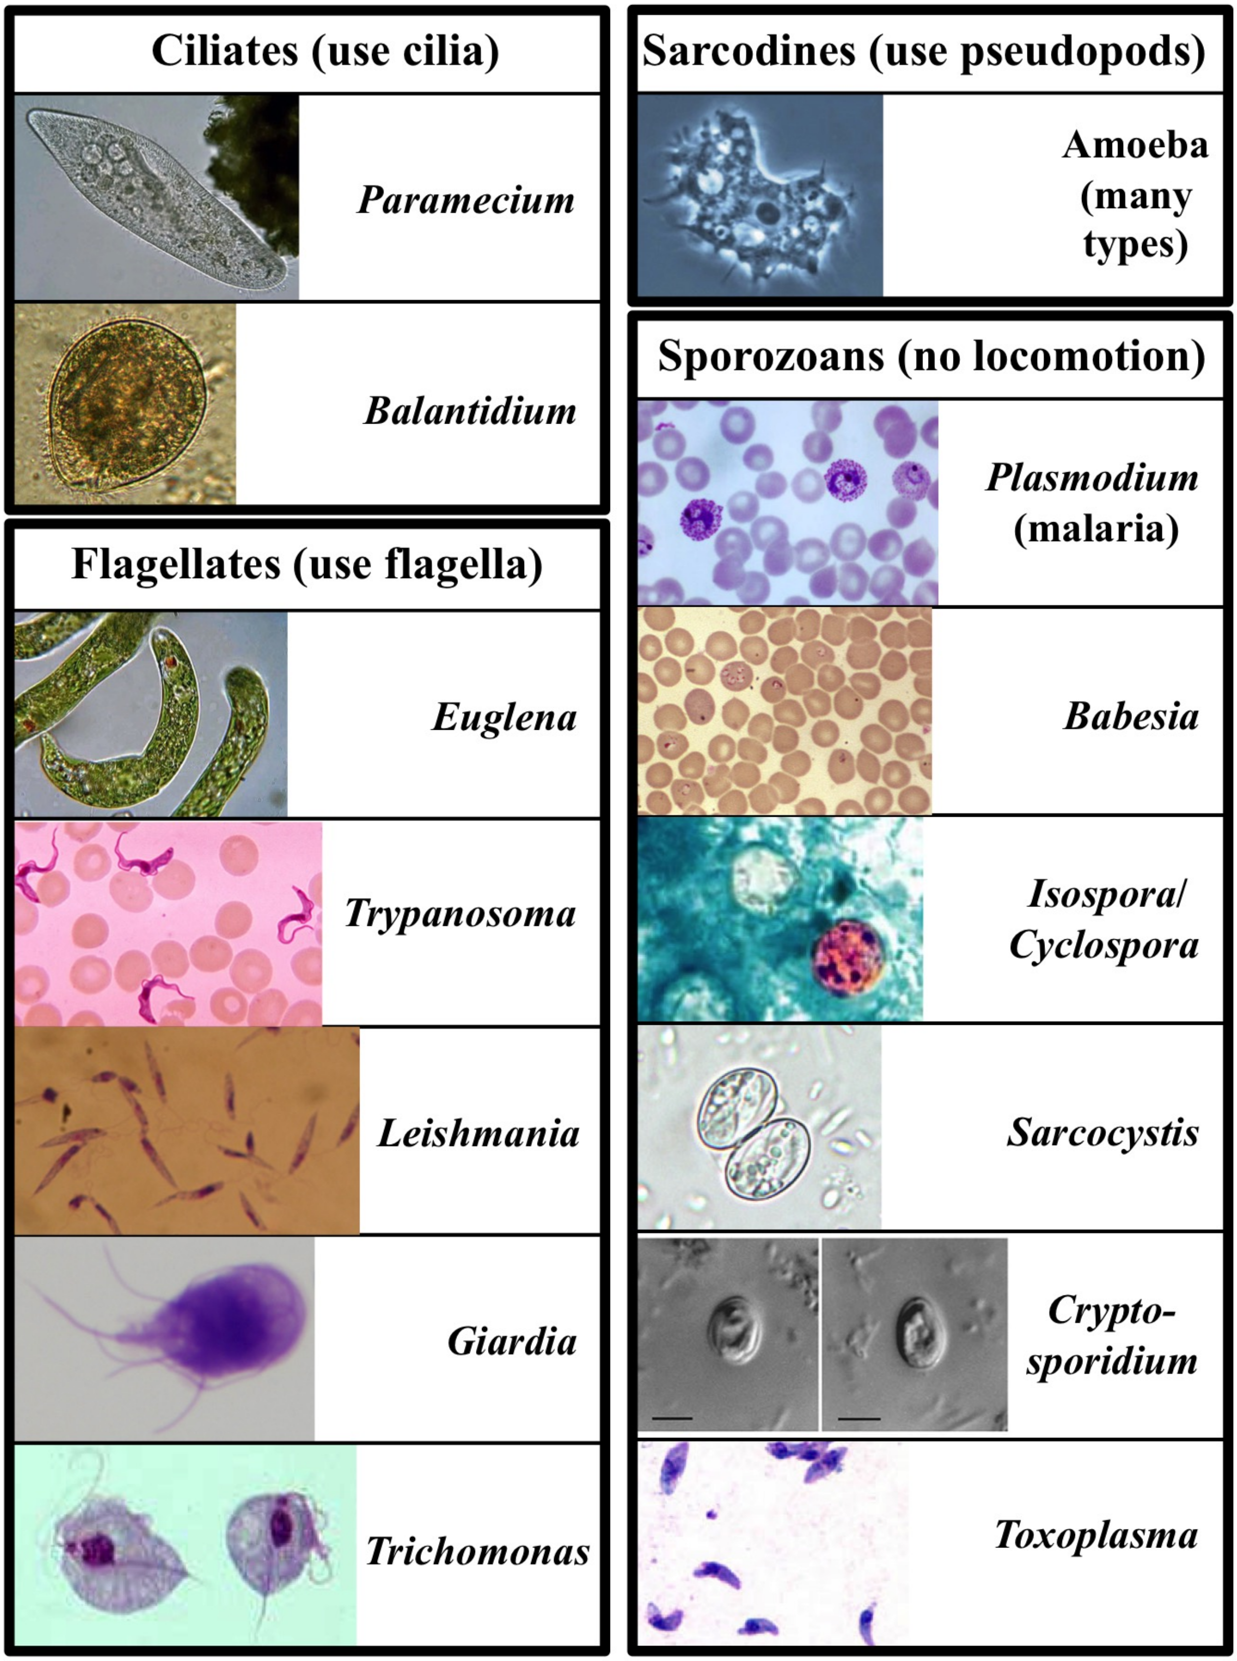
Protozoa or protists are single-celled animals, so they are eukaryotic cells that are relatively similar to human cells (Fig. 2.91). Pathogenic protozoa can take up residence in humans and cause disease either from inside or from outside our cells, whereas non-pathogenic protozoa just live harmlessly in the environment. Most protozoa can form spore-like cysts that are ∼10-20 μm wide and can lie dormant during harsh conditions in the environment, then in better conditions can hatch and grow to their mature forms, which are usually ∼20-400 μm long. Most pathogenic protozoa are transmitted from person to person either by insect bites (e.g., *Plasmodium* or malaria), *Trypanosoma*, etc.) or by ingesting contaminated water (e.g., amoeba species, *Giardia*, etc.).

Whereas German-speaking scientists made most of the major discoveries in all other categories of pathogenic microorganisms (bacteria, viruses, prions, fungi, and helminths), they made fewer important discoveries regarding pathogenic protozoa.

Many the major discoveries regarding pathogenic protozoa were made by French, British, and American doctors, presumably because those countries had large populations of citizens or subjects living in tropical or semi-tropical regions that are especially conducive to the growth of pathogenic protozoa and the insects that carry them. Historically, German-speaking countries had far less presence in such regions.

Nonetheless, Otto Bütschli (German, 1848–1920), shown in Fig. 2.92, did develop a method of categorizing protozoa that has been widely used ever since.

Perhaps most importantly, Hans Andersag (born in Italy but educated and worked in Germany, 1902–1955) developed chloroquine and related treatments for malaria in 1934, as shown in Fig. 2.93. Information on chloroquine and other antimalarial drugs was transferred to the United States and other countries during and after World War II [e.g., Pou et al. 2012; BIOS 1387]. Chloroquine-based drugs have been used worldwide ever since.



Ciliates (use cilia)
Paramecium
Balantidium
Flagellates (use flagella)
Euglena
Trypanosoma
Leishmania
Giardia
Trichomonas
Sarcodines (use pseudopods)
Amoeba (many types)
Sporozoans (no locomotion)
Plasmodium (malaria)
Babesia
Isospora/ Cyclospora
Sarcocystis
Crypto-sporidium
Toxoplasma

Figure 2.91: Protozoa or protists can be classified by their method of locomotion: ciliates use many hair-like cilia, flagellates use one or more whip-like flagella, sarcodines use pseudopods that can easily be reshaped, and sporozoans have no visible means of locomotion and simply follow the movement of the fluid they are in.

Figure 2.93: Hans Andersag developed chloroquine and related treatments for malaria in 1934.

2.2.6 Helminths

Helminths are worms. Most helminths are non-pathogenic and live in the environment. However, certain pathogenic types of helminths can invade the body of an animal or human, usually when the helminth is a microscopic egg or larva, then slowly grow to considerable size inside their new host. As shown in Fig. 2.94, helminths may be divided into three broad categories based on their shapes and structures: nematodes (roundworms), trematodes (flatworms or flukes), and cestodes (segmented tape worms). Different types of helminths attach themselves inside different organs (usually the gastrointestinal tract, but sometimes elsewhere), siphon nutrients from their host, and produce fertilized eggs that are excreted in the host's waste to infect other animals or people.

German-speaking scientists made important discoveries regarding helminth infections (Fig. 2.95).

Rudolf Virchow (1821–1902) discovered *Trichinella* nematodes, a serious problem in undercooked meat that is consumed by humans or domesticated animals.

Hans Vogel (1900–1980) discovered both *Opisthorchis* liver flukes and *Echinococcus* tapeworms.

2.2.7 Immunology

The immune system has many different ways to recognize and attack pathogenic organisms or anything else that does not appear to be normal component of the host. Some of the major types of immune system responses to pathogen infections are shown in Fig. 2.96 and include:

- T lymphocytes peer inside other cells to see if they have been infected by pathogens. If so, the T lymphocytes or T cells kill those cells and hopefully also the pathogens inside them. T cells can even activate the apoptosis pathway to persuade infected cells to kill themselves if the infected cells don't feel guilty enough to do the deed on their own. The most effective pathogens are those that can hide inside cells without being detected until it is too late to stop their evil scheme.

- B lymphocytes try to find and clobber pathogens outside our cells. B lymphocytes or B cells make antibodies, proteins that can be tailored to bind to specific pathogens but not anything else. Different B cells have different antibodies on their surface. If the antibodies on the surface of a B cell detect and bind to a specific invading pathogen, that B cell will start replicating and cranking out lots of those same antibodies to attack the pathogens. Sneaky pathogens try to avoid that response by hiding inside our cells or inside other protective enclosures, and/or by frequently changing their outer appearance so a given set of antibodies will no longer recognize them.

- Other immune system cells such as natural killer (NK) cells and macrophages destroy cells that fail to show proper identification, since they assume that those may be pathogen cells, host cells that are infected but trying to hide it, host cells that are becoming cancer cells, or other cells that are up to no good.

- Complement proteins act both by themselves and in conjunction with antibodies to bind to the surface of a pathogen and interfere with its operation.

Creators from the German-speaking world made huge contributions to the field of immunology, the study of how the immune system works and how it can be harnessed [19] Historically, immunology has been divided into cellular immunity (how cells respond to pathogens) and humoral immunity (how proteins such as antibodies and complement respond to pathogens). There is actually not a clear distinction between cellular and humoral immunity—B cells produce and release antibody proteins, antibodies and complement proteins can guide immune cells to pathogens, and there are other close interactions between cellular and humoral immunity. Nonetheless, because the distinction between cellular and humoral immunity was important during the history of the development of immunology, those terms will be used here.

Macrophage cells, natural killer cells, omplement proteins, etc. nonspecifically attack anything unfamiliar
B cells detect specific pathogens between cells and produce antibodies that bind to them

Figure 2.96: Immune system responses against infections by pathogenic microorganisms include highly pathogen-specific responses by T cells (which attack infected host cells) and B cells (which produce antibody proteins), as well as nonspecific responses by other cells and proteins that attack anything unfamiliar.

Cellular immunity

Figure 2.97 shows examples of creators who played major roles in deciphering cellular immunity.

Rudolf Virchow (German, 1821–1902) arguably made the first contributions to cellular immunity with his discoveries regarding the structure and reproduction of cells, cellular pathologies such as cancer, and cellular responses to pathologies. He strongly supported the work of later researchers such as Élie Metchnikoff on cellular immunity.

Carl Friedrich Wilhelm Claus (1835–1899) discovered and named phagocytes, cells that eat pathogens or other unwanted substances in the body.

Élie Metchnikoff (Russian but educated in Germany, 1845–1916) studied the structure and behavior of phagocytes or macrophage cells. For that research, he won the 1908 Nobel Prize in Physiology or Medicine. Professor the Count K. A. H. Mörner, Rector of the Royal Caroline Institute, noted the importance of his work [https://www.nobelprize.org/prizes/medicine/1908/ceremony-speech/]:

> Elie Metchnikoff was the first to take up consciously and purposefully, by means of experiments, the study of the question so fundamental to the question of immunity; by what means does the organism vanquish the disease-bearing microbes attacking the organism in which they have succeeded in establishing themselves and developing? At first his experiments were restricted to the lower animals. This was the case in his important work concerning a kind of infection in certain microscopic aquatic animals, the so-called water fleas. If the guiding principles behind these investigations were not known they could appear to be remote from any medical interest. They were, however, the first links in a chain of investigations leading to phenomena of immunity, also in mammals and in humans. These investigations opened the way for Metchnikoff's theory of phagocytosis. According to this theory, the microorganisms are destroyed by the activity of cells in the organism. Certain kinds of cells in the bodies of humans and animals, namely, are supposed to have, in addition to other functions, the task of catching and destroying disease-producing microbes which have succeeded in penetrating the organism, and also of rendering certain bacterial poisons harmless.
>
> I cannot here give a report on the comprehensive work and valuable observations which go to make up this theory of phagocytosis. But an important aspect of this research is that it makes a special study of certain types of cells, and that first of all the importance of the cells for the phenomena of immunity is emphasized. One can safely predict that even if other features are of more immediate importance in this doctrine, nevertheless the abundant actual observations which have been made with regard to the importance of the cells to the problem of immunity will always remain of great and permanent value. In the doctrine of immunity, as in other provinces of biology, the activity of the cells, which are considered as being the focus of organic life, remains a factor of the highest importance. The research of recent years into the question of immunity has thrown the importance of Metchnikoff's work into strong relief. As a recognition of Metchnikoff's accomplishment in initiating modern research into the question of immunity, the direction and development of which, particularly in its early stages, he profoundly influenced, the Caroline Institute wishes to honour him with this year's Nobel Prize.

Completely independently of Metchnikoff and at approximately the same time, Johann Muellendorf (German, 18??–19??) also studied macrophages and cellular immunity.

Niels Jerne (Dutch/Danish, 1911–1994) won the 1984 Nobel Prize in Physiology or Medicine for his work on both cellular and humoral immunity. Professor Hans Wigzell of the Karolinska Institute explained his discoveries [https://www.nobelprize.org/prizes/medicine/1984/ceremony-speech/]:

> Niels Jerne is the great theoretician in modern immunology. He entered the immunological arena comparatively late in his life and was 44 years old when in 1955 he published his first important theory of the construction of the immune system. Jerne proposed that the well-known capacity of the immune defence to recognize myriades of foreign molecules was something predetermined, already existing in the body when the very first contact with a foreign structure was made. What then happened was merely a selection amongst the naturally occurring antibody population resulting in an increase in production of exactly those antibodies which happened to have a good fit for the structure. Jerne's theory stood in great contrast to prevailing theories at that time, but it was rapidly confirmed and extended. We now know that Darwin's laws about natural selection indeed apply to the cells of the immune system: Those cells which happen to have received the property to produce a wanted antibody type will upon vaccination be rewarded with regard to proliferative capacity and survival.
>
> Jerne took another known feature of the immune defence as the starting point for his next important theory, in 1971. The immune system always expresses a very strong defence of the private and unique features of the tissues within one individual. This behaviour creates great problems whenever attempts are made to transplant tissue from one individual to another. Jerne assumed that the molecules in the tissues that cause these reactions, the so-called transplantation antigens, must have their normal functions within the body of the individual. He proposed that one function of these molecules could be to serve as a specific driving force for the cells of the immune system, thus creating a large number of cells from which cells especially suitable to defend the tissues of the host would become selected. Special organs, such as the thymus, were assumed to serve as a combination of greenhouse and university for these cells. In this theory Jerne did predict to a great extent how the specificity of the cellmediated immunity is generated.
>
> In the third great theory, in 1974, Niels Jerne introduced us to the mirror halls of immunology. The immune system is visualized somewhat like a gigantic computer where constant communication and regulation takes place in between the different components, the cells. The number of cells in such a network system in an adult human being exceeds 1012 (one million millions); and the system has through its capacity to produce billions of different forms of antibodies an enormous inbuilt richness with regard to structural variations. Jerne proposed that this should allow the creation of multiple complementary situations where certain antibodies would have select capacity to combine with their mirror images. Some antibodies would according to the theory then even mimic foreign molecules against which other antibodies would normally be produced during immunization. Jerne postulated that pairs of antibodies and their mirror images would spontaneously be produced during the development of the immune system, thus creating the possibilities for communication networks and regulatory equlibria. During immunization the foreign molecules would enter the mirror halls of immunology where the

> different pairs of antibodies and cells would perform their interdependent piruettes and separate the partners chasing away the mirror images. This change in equilibrium would then serve as a driving force, resulting in immunity. It is now well documented that network forces of the fascinating type that Jerne predicted do indeed exist inbuilt in our own immune systems. The theory also predicted the almost mind-boggling possibility that antibodies of the mirror image-type could replace the foreign material completely when inducing immunity. This is now a proven reality. Thus, it is for instance possible to induce a long lasting immunity against hepatitis virus by immunization with mirror image antibodies to the antibodies against hepatitis virus without ever using the virus in the vaccination.
>
> In conclusion, Niels Jerne has via his visionary theories enabled modern immunology to make major leaps of progress. Several concepts in immunology now considered as self-evident have their roots in some of his pioneering thoughts.

Rolf Zinkernagel (Swiss, 1944–) made important discoveries regarding T cells, for which he won the Nobel Prize in Physiology or Medicine in 1996 (along with Peter Doherty). The Royal Swedish Academy of Sciences summarized this work [https://www.nobelprize.org/prizes/medicine/1996/zinkernagel/facts/]:

> When the body's cells are attacked by viruses, the immune system begins killing the infected cells. By studying mice, Rolf Zinkernagel and Peter Doherty proved in 1973 how the immune system recognizes virus-ridden cells. A kind of white blood cell, T-cells, kills the virus-ridden cells, but only if they recognize both the foreign substances, viruses, and certain substances from the body's own cells. The discovery has provided an important basis for vaccines and medicines for infectious diseases, but also for inflammatory diseases and cancer.

Humoral immunity

Figure 2.98–2.99 shows examples of creators who played major roles in discovering and elucidating humoral immunity.

Joseph Fodor (Hungarian, 18??–19??) discovered the first indications of complement protein activity in 1886.

Hans Buchner (German, 1850–1902) demonstrated and studied complement proteins in 1891. He was the older brother of Eduard Buchner (p. 129).

Paul Ehrlich (German, 1854–1915) made important discoveries regarding the humoral immune system and how it could be harnessed. He won the 1908 Nobel Prize in Physiology or Medicine for that work. Professor the Count K. A. H. Mörner, Rector of the Royal Caroline Institute, praised Ehrlich's discoveries [https://www.nobelprize.org/prizes/medicine/1908/ceremony-speech/]:

> It has been shown that protection against disease can be of two kinds. It can consist in the ability to destroy microbes or to inhibit their further development. This is a bacteria-destroying immunity. But there is also a protection of another kind, one which acts against the bacteria products. The damage which the disease-producing microorganisms cause, namely, is conditioned by the poisons which these organisms produce and which are distributed by the body fluids. A certain kind of immunity occurs against this danger as well, namely the so-called poison immunity. The best known example of this is the use of anti-diphtheria serum, when, through serum injection, substances are introduced into the organism which act as antitoxins against the diphtheria poison. It has been discovered that poisons which are produced by bacteria have the property, as have many other substances also, of causing the production of elements in the organism which have an antagonistic effect especially and exclusively directed against the substance which caused the production of the elements. This we call the formation of antibodies. After immunity has been achieved, such antibodies are found in the humors of the organism. Furthermore, it has been possible to show that these antibodies are of great importance, not only as regards protection against disease-producing microorganisms themselves, but also, above all, as regards protection against the toxic products of these organisms. [...]
>
> A man who has been responsible for important scientific progress as organizer and leader in this field deserves to be mentioned among the first of those who have dedicated themselves to a study of immunity, is the research scientist Paul Ehrlich, already famous for his other biological work, and the Professorial Staff of the Caroline Institute wishes to honour him too with this year's Nobel Prize for his work in the sphere of immunity.

Emil von Behring (German, 1854–1917) demonstrated that therapeutic antibodies could be produced by one individual and administered to another individual to combat a particular pathogen. For that work, he won the Nobel Prize in Physiology or Medicine in 1901. Professor the Count K. A. H. Mörner, Rector of the Royal Caroline Institute, explained the importance of von Behring's research [https://www.nobelprize.org/prizes/medicine/1901/ceremony-speech/]:

> In general, the disease-causing bacteria produce poisons which in their turn give rise to

> a toxic condition in the individual in which they develop. And it is precisely because of these poisons that the bacteria are so dangerous. Nevertheless, it has been shown that the poisons, under certain conditions, will lead the organism to produce substances which render them harmless and which prevent the development of the bacteria. When such a condition of "immunity" has been built up, the individual can become insensitive to the bacteria in question and resistant to the poisons. [...]
>
> Blood fluid—or blood serum—from an individual who has been immunized with poisons from a certain bacterium, can, namely, when introduced into the organs of another individual, confer resistance upon him against the bacterium in question. Upon this fact modern serum therapy is based.
>
> Up until now, serum therapy has had particularly splendid triumphs in the case of diphtheria, but its significance is not limited to this disease but extends much further. The field which is opened up for research by the development of serum therapy has therefore—for the present—no discernible limits. Much ground has been gained already and we are justified in expecting a great deal of important progress.
>
> The pioneer in this new area of medical research, Professor Emil von Behring, has been chosen by the Professorial Staff of the Caroline Institute as the recipient of this year's Nobel Prize for Medicine.

Richard Pfeiffer (German, 1858–1945) made many important discoveries in microbiology and immunology during his long career. He developed both therapeutic antibodies and vaccines for several bacterial infections, including cholera and typhoid.

Julius Morgenroth (German, 1871–1924) worked closely with Paul Ehrlich and also conducted his own research on immunology and therapeutics for infections.

Fritz Breinl (German?, 1888–1936) and Felix Haurowitz (Czech, 1896–1987) conducted experiments on antibody formation and developed theoretical models of the process.

To complete the story even though this is a little later than the primary time period for this book, Georges Köhler (German, 1946–1995) developed the hybridoma method for producing large amounts of identical (monoclonal) antibodies for diagnostic or therapeutic applications (along with César Milstein). For that innovation, he won the Nobel Prize in Physiology or Medicine in 1984. Professor Hans Wigzell of the Karolinska Institute noted [https://www.nobelprize.org/prizes/medicine/1984/ceremony-speech/]:

> At the same time the young researcher Georges Köhler struggled in Basel in Switzerland to study normal antibody-producing cells in tissue culture. His research was in part frustrating as he could only get very few cells to survive for short periods of time. Köhler knew of the important studies of Milstein, and it seemed logical to see if normal antibody-forming cells could be fused with tumor cells to produce long-lived hybrid cell lines. If this was indeed possible the experiments of Milstein would indicate that they should then continue to produce their antibodies. At the same time the normally evil feature of tumor cells, the capacity to proliferate for ever, would now be turned into a

very beneficial feature. Köhler went to Milstein's laboratory and together they wrestled with the problems and managed to solve them in a hectic two year period, 1975–1976. By that time they had succeeded to develop a technique allowing them at will to fish up exactly those rare antibody-producing cells that they wanted from a sea of cells. These cells were fused with tumor cells creating hybrid cells with eternal life and capacity to produce the very same antibody in high quantity. Köhler and Milstein called these hybrid cells hybridomas, and as all cells in a given hybridoma come from one single hybrid cell, the antibodies made are monoclonal.

Köhler's, and Milstein's development of the hybridoma technique for production of monoclonal antibodies have in less than a decade revolutionized the use of antibodies in health care and research. Rare antibodies with a tailor-made-like fit for a given structure can now be made in large quantities. The hybridoma cells can be stored in tissue banks and the very same monoclonal antibody can be used all over the world with a guarantee for eternal supply. The precision in diagnosis is greatly improved, and entirely new possibilities for therapy have been opened up via the hybridoma technique. Rare molecules present in trace amounts in complex solution can now be purified in an efficient manner using monoclonal antibodies. In all, it is therefore correct to describe the hybridoma technique discovered by Georges Köhler and César Milstein as one of the major methodological advances in medicine during this century.

Immunoassays

As illustrated in Fig. 2.100, immunoassays use antibodies (produced by B cells) that bind to specific pathogens but nothing else. Each antibody is a Y-shaped protein, with an identical pathogen binding site at the top of each prong of the Y. If the corresponding pathogen is not present in a sample, nothing happens, but if it is, antibodies and pathogens bind to each other and create a detectable clump. Immunoassays are now used for a wide variety of medical diagnostics and biotechnology applications.

Creators from the German-speaking world, shown in Fig. 2.100, developed immunoassays to test for the presence of specific pathogens *in vitro* (in test tubes):

- Max von Gruber (Austrian, 1853–1927) discovered the agglutination reaction, in which antibodies and pathogens clump together, in 1896.
- Rudolf Kraus (Austrian, 1868–1932) used the agglutination reaction to create an antibody assay for specific bacterial precipitins in 1897.
- August von Wasserman (German, 1866–1925) used similar methods to create a complement fixation test for syphilis bacteria in 1906.
- Similar *in vitro* immunoassays were rapidly developed for a wide variety of other pathogens or other targets for detection.

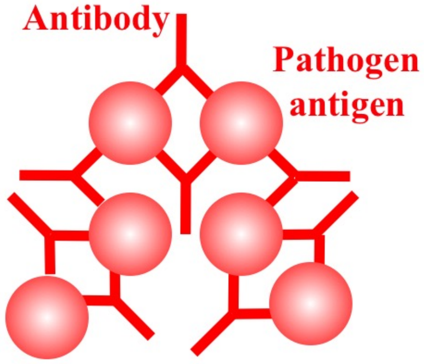
As shown in Fig. 2.101, creators from the German-speaking world also developed immunoassays to test for the presence of specific pathogens *in vivo* (directly in the body of a patient):

- Clemens von Pirquet (Austrian, 1874–1929) developed the skin test for tuberculosis in 1906, and it has been widely used ever since.
- Béla Schick (Hungarian, educated and worked in Austria, 1877–1967) developed a skin test for diphtheria susceptibility in 1910. The method became known as the Schick skin test and was used worldwide.
- Similar *in vivo* immunoassays were quickly developed for a wide variety of other pathogens or allergic reactions.

In vitro immunoassays

Distinguish antigens (components) from pathogens vs. non-pathogens, or from one pathogen vs. other pathogens

Antibody proteins form visible clumps if they recognize a specific pathogen antigen



Antibody proteins do not form clumps if they do not recognize any pathogen antigens

Schick skin test

Figure 2.101: Clemens von Pirquet and Béla Schick harnessed components of the immune system to create *in vivo* (in the body) immunoassays for specific pathogens.

Vaccines and adjuvants

Vaccines are another way to artificially harness the immune system. Vaccines teach the immune system what specific pathogens to keep watch for, like showing a “wanted” poster to the police (Fig. 2.96). A good vaccine looks like a certain pathogen to the immune system, yet does not do any pathogenic mischief itself. Most vaccines use killed versions of the target pathogen, artificially weakened versions of the target pathogen, or individual pieces of the target pathogen.

As already noted, German-speaking creators produced many of the first vaccines. (Louis Pasteur in Paris played an enormous role too of course.) Peter Plett developed and demonstrated the first cowpox-based vaccine for smallpox (p. 191). Otto Waldmann, Gottfried Pyl, and Carl Köbe created a vaccine for foot-and-mouth disease virus (p. 197). Poliovirus was discovered by Karl Landsteiner and Erwin Popper, and cultured in cells by Marguerite Vogt, which were essential steps to creating vaccines for polio (p. 201). Many other examples could be cited as well.

German-speaking creators also developed methods to make vaccines more effective, as shown in Fig. 2.102. Jules Freund (Hungarian, educated and worked in Austria and Germany, 1890–1960) introduced chemical adjuvants (additives) to make vaccines more potent. In 1957, Jean Lindemann (Swiss, 1924–2015) discovered (along with Alick Isaacs) interferon, a natural hormone that can provoke a strong immune system response.

2.3 Neuroscience

German-speaking scientists largely dominated the early history of neuroscience, the study of how the brain, senses, nerves, and muscles work.[20] Neuroscience is a very large and diverse field; for convenience, it is divided into several (overlapping) subfields in this section:

2.3.1. Brain regions

2.3.2. Neurons

2.3.3. Neurotransmitters

2.3.4. Animal behavior

2.3.5. Circadian rhythms

2.3.6. Electroencephalography (EEG)

2.3.7. Neuropathology and neuropsychiatry

2.3.8. Psychology and psychotherapy

2.3.9. Analgesics and anesthetics

2.3.10. Vision

2.3.11. Hearing and balance

2.3.12. Touch

2.3.13. Taste

2.3.14. Smell

2.3.1 Brain Regions

Apart from the French physician Pierre Paul Broca (1824–1880), most of the scientists who worked to decipher which regions of the brain perform which functions came from the greater German-speaking world (Figs. 2.103–2.106).

---

[20] Bielka 2002; Deichmann 1996; Dominguez-Lacasa 2005; Finger 1994; Gausemeier 2005; Gedeon 2006; Jahn 2004; Junker 2004; Koesling and Schülke 2010; Kohler 2008; Magner 2002; Pasternak 2004; Possehl 1989; Raviña and Kubinyi 2011; Schnalke and Atzl 2010; Schneider 1972; von Schwerin 2013; Simmons 2002; Roger Smith 1997; Sneader 2005; Weatherall 1991.

Franz Joseph Gall (German states, 1758–1828) and Johann Spurzheim (German states, 1776–1832) were two of the first scientists to systematically investigate the localization of brain functions.

Friederich Goltz (German, 1834–1902) used surgical methods to study the functions of regions of the cerebral cortex in dogs' brains.

Gustav Fritsch (German, 1838–1927) and Eduard Hitzig (German, 1838–1907) used electrical stimulation to investigate the functions of different areas of dogs' brains.

Hermann Munk (German, 1839–1912) studied the functions of different parts of the brains in dogs and monkeys.

Carl Wernicke (German, 1848–1905) identified the region of the human brain that is involved in comprehending language, now known as Wernicke's area.

Constantin von Monakow (Russian, studied and worked in Switzerland, 1853–1930) spent his career studying neuroanatomy and neural functions.

Jacques Loeb (German, 1859–1924) applied electrical stimulation to localized areas of dogs' brains and conducted experiments in other areas of biology. He moved to the United States and became a champion of improving science research there.

Korbinian Brodmann (German, 1868–1918) identified 52 distinct regions of the cerebral cortex, which are now called Brodmann areas. Brodmann studied the macroscopic and microscopic features of each area, as well as its functions.

The spouses Oskar Vogt (German, 1870–1959) and Cécile Vogt-Mugnier (French but worked in Germany, 1875–1962) were pioneers in neuroanatomy and electrical stimulation of the brain. They were assisted by Max Borcherdt (German?, 18??–19??) and Louise Bosse (German?, 18??–19??), among others.

Walter Rudolf Hess (Swiss, 1881–1973) was another pioneer in using electrodes for mapping the locations and functions of brain regions. For that work, he won the Nobel Prize in Physiology or Medicine in 1949. Professor H. Olivecrona of the Royal Caroline Institute explained Hess's research [https://www.nobelprize.org/prizes/medicine/1949/ceremony-speech/]:

> Although we have long been aware of the function of the midbrain as a higher center of the autonomous nervous system, we have only now, through the research of Walter Rudolf Hess, had the localization of these functions mapped out in detail. Through the use of a refined and accurate technique he has succeeded in applying stimulation to or causing the destruction of very small areas, and thus he has been able to study the effect of the stimulus, as well as of the disappearance of a function. For his experiments he has used cats into which, under anesthesia, a thin metal wire has been introduced. The wire has been electrically insulated along its entire length except at the very end, which has been placed in the center of the brain area which is being studied. When the animal has regained consciousness and has recovered entirely from the effect of narcosis, it is possible to stimulate the area of the midbrain where the end of the needle is situated by

> conducting a weak electric current through the metal wire. There were various effects, depending upon the location of the needle-end, each effect always connected to one definite center of stimulation. By electrical stimulation of certain strictly limited parts of the midbrain it was possible to reproduce spontaneous autonomous functions. By stimulating one definite part, the animal was caused to curl up and go into a sleep from which it could be awakened just as easily as from natural sleep. Stimulation of other areas gave rise to defensive reactions which would normally occur if the cat were threatened by a dog: the hairs on the back stood up on end, the tail was ruffled, the cat spat and, if the stimulus was not discontinued, it attacked. Other localizations of the stimulus caused evacuation of the intestines or the bladder, accompanied by the characteristic body postures. From other areas, blood circulation and respiration could be influenced. It was common to all these experiments with stimuli that they released complex functions, not limited to the reactions characteristic of the autonomic nervous system, such as evacuation of the intestines, secretion of saliva, changes of the pupils, and the like, but were accompanied by reactions of the skeletal muscles necessary and appropriate to the autonomic function, such as characteristic body postures, attempts at escape or attack, and so forth. It was apparent from these facts that in the midbrain we have higher centers of autonomic functions which coordinate these with reactions of the skeletal musculature adapted to the individual functions. An ingenious method made possible the exact determination of the anatomic localization after the discontinuance of the experiment, and thus the anatomic substrata of complex autonomic functions could be mapped out. Through his research Hess has brilliantly answered a number of difficult questions regarding the localization of body functions in the brain.

Johannes Dusser de Barenne (Dutch, 1885–1940) injected strychnine into different regions of the cerebral cortex in order to determine their functions.

2.3.2 Neurons

The brain is composed of cells, and the predominant types of brain cells are called neurons, as illustrated in Fig. 2.107. (There are also glial cells, which assist and care for the neurons, and also appear to play direct roles in thinking that are still not well understood.) Thought impulses or signals travel within a given neuron as an electrical signal, called an action potential. Signals are usually sent from one neuron to other neurons as chemical molecules or neurotransmitters that are released by one neuron and detected by its immediate neighbors.

Other than the extraordinarily farsighted and far-reaching work of the Spanish scientist Santiago Ramón y Cajal (1852–1934) and the staining methods of the Italian histologist Camillo Golgi (1843–1926), most of the early research on individual neurons occurred in the German-speaking world.

Johann Purkinje (Austrian/Czech, 1787–1869) discovered what are now called Purkinje cells in the cerebelllum. He also discovered what are now called Purkinje fibers that conducted electrical impulses in the heart.

Rudolf Wagner (German states, 1805–1864) studied neurons, neuroanatomy, and electric eels.

Rudolf von Kölliker (Swiss, 1817–1905) employed staining methods to study neuron pathways in the inner brain and the spinal cord.

Leopold Auerbach (German, 1828–1897) discovered what is now called Auerbach's plexus, a bundle of neurons linked to the gastrointestinal tract.

Heinrich Wilhelm von Waldeyer-Hartz (German, 1836–1921) conducted research on neurons and in fact coined the word "neuron" to describe individual brain cells.

Heinrich Lissauer (German, 1861–1891) discovered what is now called Lissauer's tract, neural fibers in the posterolateral tract of the spinal cord.

Ludwig Guttmann (German, 1899–1980) pioneered the treatment of spinal injuries.

Emil du Bois-Reymond (German, 1818–1896) discovered the action potential (the propagation of an electrical signal in a neuron) in 1843.

Hermann von Helmholtz (German, 1821–1894) measured the conduction velocity of action potentials in 1850.

In 1902, Julius Bernstein (German, 1839–1917) realized that the action potential involved calcium ions passing through the cellular membrane.

In 1949, Bernhard Katz (German, 1911–2003) also considered the effect of other types of ions on the action potential.

Bert Sakmann (German, 1942–) and Erwin Neher (German, 1944–) invented and used the patch clamp technique to measure the electrical current from individual ion channels in neurons and other cell types (Fig. 2.110). For that work, they won the Nobel Prize in Physiology or Medicine in 1991. Professor Sten Grillner of the Karolinska Institute explained their discoveries [https://www.nobelprize.org/prizes/medicine/1991/ceremony-speech/]:

> Ions are transported through ion channels, which can be specific to one type of ion like sodium or potassium. Every single ion channel consists of one protein molecule or a molecular complex, which forms the walls of a thin channel, connecting the interior of the cell with its exterior. The ion channel has such a small diameter that it corresponds to the width of only one single ion, and it is thus incredibly small. The ion channel is opened or closed as its molecule changes shape. When, for example, the ion channel molecule for sodium is opened, sodium ions in a long row will pass through the minute ion channel into the cell, because there are more sodium ions outside the cell than on the inside. Since ions are electrically charged, an electric current will also pass through the open ion channel. This year's Laureates, Erwin Neher and Bert Sakmann, succeeded in making a conclusive demonstration that ion channels exist, by developing a technique by which the miniscule currents, flowing through a single ion channel molecule, could be measured. These are currents of a thousandth of a billionth of an ampère. The technique is nevertheless, in principle very simple. A thin glass-tube filled with fluid is used as a recording electrode. The tip of the tube is pulled out to a width of only some thousandth of a millimeter. When it is brought in very close contact with the cell membrane, they form as it were, a chemical unity with each other. The ion channels, which are present in the cell membrane under the pipette opening, will then form the only connection between the interior of the cell and its outside. When one of the channels is opened a very small current will flow, which can be measured through the ingenious technique of Neher and Sakmann. We can thus measure exactly when a single ion channel is opened or closed, that is when a single molecule changes its shape. This is a totally unique level of resolution. This technique was combined with the new methods for biochemical microsurgery on single molecules, through which different parts of the ion channel molecules can be modified or exchanged. Through this procedure, it has been possible to elucidate the function of the different parts of the molecule, for instance, what makes an ion channel select only one type of ion, or be sensitive to a particular type of chemical transmitter. This technique has in one single blow changed our ability to study the different ion channels, which influence the life of every little cell. Thousands of laboratories throughout the entire world now use this technique to understand the roles ion channels may play in different tissues in animals or plants. Ion channels are, for instance, engaged when the cells in the pancreas secrete insulin, when the heart is contracting, or when we think or remember something. A number of diseases are either influenced or caused by a modified ion channel function. Many drugs act directly on the specific type of ion channel, which is of importance in a particular disease. Examples include anxiety, cardiovascular disease, epilepsy, and diabetes. Our life as a unique individual actually starts with an activation of the ion channels in the egg cell by the sperm at the instant of conception. This prevents other competing sperms from gaining access to the egg cell.

2.3.3 Neurotransmitters

As shown in Fig. 2.111, chemical molecules or neurotransmitters carry signals across the synapse (gap) between the end (axon) of one neuron and the beginning (dendrite) of the next neuron. Different types of neurons produce and respond to different types of neurotransmitters, such as acetylcholine, dopamine, histamine, and norepinephrine.

Scientists from the German-speaking world made many significant contributions to knowledge about neurotransmitters (Figs. 2.112–2.113).

Hermann Blaschko (German, 1900–1993) worked out the synthetic pathway for dopamine, norepinephrine, and epinephrine in 1939 (independently of Peter Holtz).

Daniel Bovet (Swiss, 1907–1992) discovered antihistamines, drugs that block histamine-mediated signals and that have been widely used since then to control allergic reactions. He won the Nobel Prize in Physiology or Medicine in 1957. Professor B. Uvnäs of the Royal Caroline Institute noted [https://www.nobelprize.org/prizes/medicine/1957/ceremony-speech/]:

> Daniel Bovet concentrated his research on the problem of pharmacologically blocking the amines mentioned above, and he succeeded in producing substances which specifically inhibited their effects.
>
> As early as 1937, Bovet and Staub succeeded in producing the first antihistamine, thymoxidiethylamine, capable of preventing anaphylactic shock in animals which, unneutralized, was fatal. This first histamine antagonist was, it is true, too toxic to be used clinically, but virtually every antihistamine that is used throughout the world today to oppose symptoms of allergy is derived from it. [...]
>
> For a number of years, Bovet and his co-workers studied in animals the relationships between chemical structure and biological effect, as could be observed in the alkaloids of curare and ergot. Proceeding by systematic variations and successive simplifications of chemical structure, work which involved the elaboration of new methods of biological testing and the production of hundreds of new synthetic chemical compounds, they succeeded, by degrees, in obtaining simple chemical compounds which proved themselves, from the point of view of specificity and the absence of undesirable side-effects, much more useful than naturally occurring substances.
>
> The interest which the appearance of products capable of paralysing muscle presents in practical medicine is bound to the evolution of modern surgery, which has made it possible to perform more and more complicated surgical procedures. Operations of this type often require complete muscular relaxation. Anaesthesia must therefore be deep and long, and for this reason it carries risks which can be more dangerous than the surgery itself. We owe to Bovet's research the general muscle relaxants which we use today. We can, in this way, use a light level of anaesthetic and reduce the hazards to which the patient is subjected. Sympatholytic compounds have not yet found any application in general medicine. The future will tell whether the hopes placed in them will be fulfilled and whether they will be of value in the treatment of hypertension and

> other vascular conditions for which we think a reduction in nervous control would be desirable.
>
> Apart from the importance of Bovet's work in experimental neuropharmacology, his observations have exerted a very stimulating influence in one rapidly growing branch of pharmacology: I speak of psychopharmacology. Biological amines are the transmitters of nerve impulses in the different tracts of the brain, just as they are the chemical agents which link nerve fibres to peripheral organs. In other words, it should be possible to find drugs which specifically affect brain function.

Edith Bülbring (German, 1903–1990) studied the effects of acetylcholine, epinephrine, and serotonin on muscles.

Wilhelm Feldberg (German, 1900–1993) conducted experiments involving histamine, acetylcholine, and other neurotransmitters.

Peter Holtz (German, 1902–1970) worked out the synthetic pathway for dopamine, norepinephrine, and epinephrine in 1939 (independently of Hermann Blaschko).

Bernhard Katz (German, 1911–2003) studied how acetylcholine is released from neurons at synapses. For his discoveries, he won the Nobel Prize in Physiology or Medicine in 1970. Professor Börje Uvnäs of the Nobel Committee for Physiology or Medicine explained Katz's research [https://www.nobelprize.org/prizes/medicine/1970/ceremony-speech/]:

> Bernhard Katz was specially interested in the electrical events which occur when impulses in motor nerves induce muscle activity by acting at motor end-plates. These special structures in the muscle with condenser-like properties are charged by the nerve impulses and their discharge in turn activates the muscle. Through the discovery of the existence of "miniature end-plate potentials" Katz demonstrated that the messenger substance between the motor nerve and the muscle end-plate, acetylcholine, was released from the nerve terminals in small quanta, small packages if you like.

Max Lewandowsky (German, 1876–1916) studied epinephrine and other neurotransmitters, and named the "blood-brain barrier" that only allows certain substances in the bloodstream to enter the brain.

Otto Loewi (German, 1873–1961) discovered the neurotransmitter acetylcholine. For that accomplishment, he won the Nobel Prize in Physiology or Medicine in 1936. Professor G. Liljestrand of the Royal Caroline Institute praised Loewi's research [https://www.nobelprize.org/prizes/medicine/1936/ceremony-speech/]:

> While the idea that nerve stimulation could be brought about by the release of certain substances was not entirely new, it is nevertheless thanks to Loewi that the idea was brought from the realm of unproven hypotheses on to the firm ground of certain experience. He first used a heart with its nerve trunk, removed from a frog or toad, connecting up the heart chamber with a small glass container in which was a small quantity of a suitable nutrient fluid. If the nerve trunk was stimulated by electrical means, the number and strength of heart beats altered according to circumstances there are, namely,

> in the nerve trunk fibres from both the sympathetic and the parasympathetic systems. If after such stimulation Loewi transferred the fluid which had been pumped in and out of the heart into another similarly prepared heart, he found that the fluid itself had taken on properties capable of producing changes in the activity of the organ corresponding to those which had earlier been produced by the nerve stimulation. Through this very simple but ingenious experiment it was proved that the nerve stimulus can release substances having the action characteristic for the nerve stimulation and further observations left no doubt whatever that the nerve stimulus itself was passed on to the organ by chemical means.
>
> Painstaking work now began with the object of determining the nature of the substances concerned—it was soon apparent that different substances were involved in the stimulation of the two different kinds of nerves. This task would appear hopeless considering the incredibly small quantities in which the substances are released. Chemical methods alone were of no avail. But Loewi carried out instead a model analysis, using those activities which were obtained in the living organism under changing conditions. With the sympathicus substance he was able to prove in this way that, in a series of important points such as destruction through oxidation and under the effects of certain kinds of irradiation, as well as in regard to its action, it corresponded absolutely with adrenaline. As regards the parasympathetic substance, the task was more difficult on account of its rapid breaking down in the presence of blood and tissue—this supports the contention made previously that the parasympathetic nerves act locally whereas the action of the sympathetic nerves is more widespread. Loewi and Navratil discovered that the breaking down could be prevented by the addition of the vegetable base physostigmine and this made it possible to work out a method which later made the detection of the substance very much easier. After considerable work, Loewi was able to determine the nature of this substance too, and to prove that the parasympathetic substance was identical with acetylcholine.

David Nachmansohn (German, 1899–1983) focused on acetylcholine, especially at junctions between neurons and muscles.

Marthe Vogt (German, 1903–2003) was appointed head of the chemical division of the Kaiser Wilhelm Institute for Brain Research when she was only 28 years old; she later fled the Third Reich and continued her work in the United Kingdom. During her long career, she studied epinephrine, acetylcholine, and other neurotransmitters.

2.3.4 Animal Behavior

Several scientists from the German-speaking world made especially noteworthy contributions to knowledge about animal behavior (Figs. 2.114–2.117):

- Carl Hagenbeck (German, 1844–1913) designed, patented, and built the first modern zoos, giving the animals much larger and much more realistic environments and separating visiting humans from the animals by height or unbridged gaps instead of bars or glass. He also spent a great deal of his time studying and training animals, and his more natural, modern zoos made animals available for others to study.

- Ernst Mayr (German, 1904–2005) spent decades studying bird behavior and bird evolution, as well as the more general principles of evolution.

- Karl von Frisch (Austrian, 1886–1982) studied the behavior of bees, for which he won the Nobel Prize in Physiology or Medicine in 1973.

- Erich von Holst (Baltic German, 1908–1962) studied the neuroscience and muscle movements of birds, flying insects, worms, and other animals.

- Konrad Lorenz (Austrian, 1903–1989) monitored and analyzed the behavior of birds. For that work, he won the Nobel Prize in Physiology or Medicine in 1973. Lorenz worked with Tinbergen for part of his research.

- Konrad Most (German, 18??–19??) developed systematic methods for training police and military dogs, and published them in his 1910 book, *Abrichtung des Hundes*, or *Training of Dogs* [Burch and Pickel 1990].

- Carl Spitz (German, 1894–1976), one of Konrad Most's students, moved to the United States, where he trained "Toto" (real name Terry) for *The Wizard of Oz*, as well as other dogs featured in films. Spitz also ran the U.S. program for training military dogs during World War II [http://akc.libraryhost.com/repositories/2/archival_objects/11098].

- Nikolaas Tinbergen (Dutch, 1907–1988) observed and tested the behavior of a wide variety of animals, including birds, fish, and bees. For his discoveries, he won the Nobel Prize in Physiology or Medicine in 1973. Tinbergen worked with Lorenz for part of his research.

Professor Börje Cronholm of the Karolinska Institute explained the importance of the work of von Frisch, Tinbergen, and Lorenz [https://www.nobelprize.org/prizes/medicine/1973/ceremony-speech/]:

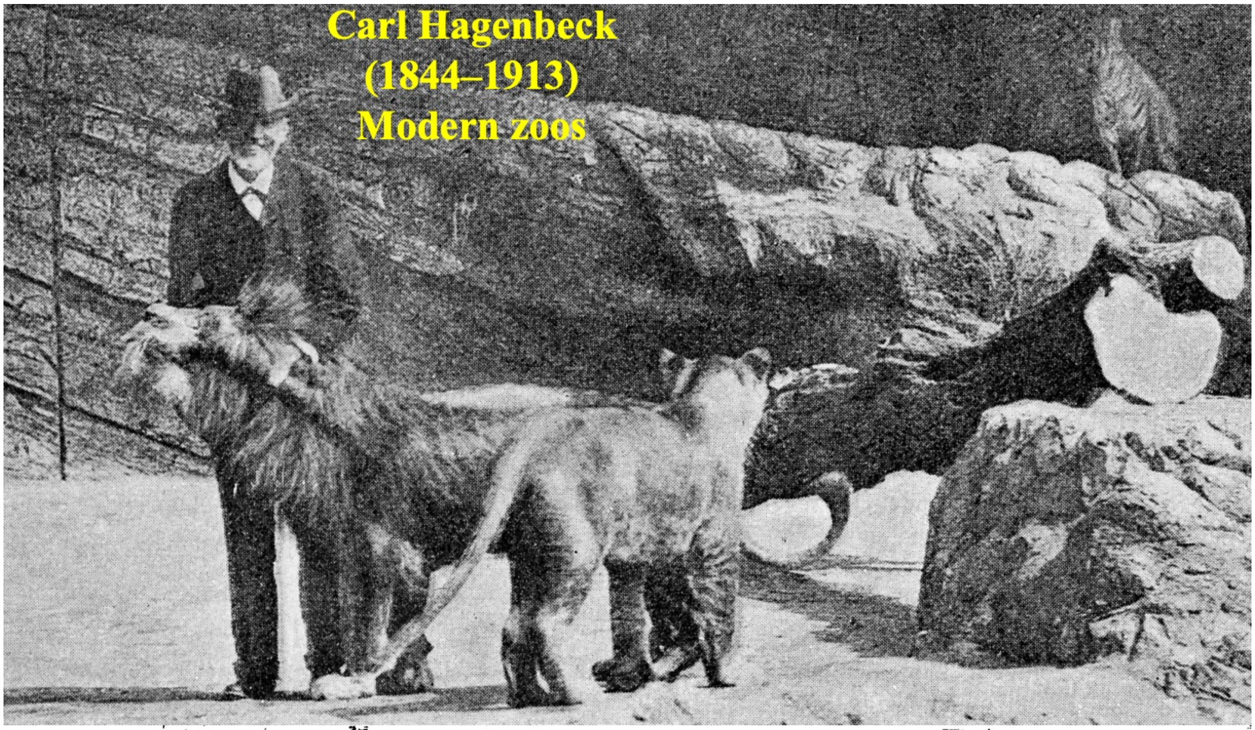
> For more than sixty years: Karl von Frisch has devoted himself to studies of the very complicated behavior of honeybees. Above all, he has elucidated what has rightly been called 'the language of bees'. When a bee has found flowers containing nectar, it performs a special dance when returning to the hive. The dance informs the bees in the hive of the existence of food, often also about the direction where the flowers will be found and about the distance to them. The foraging bee is able to indicate the direction of the

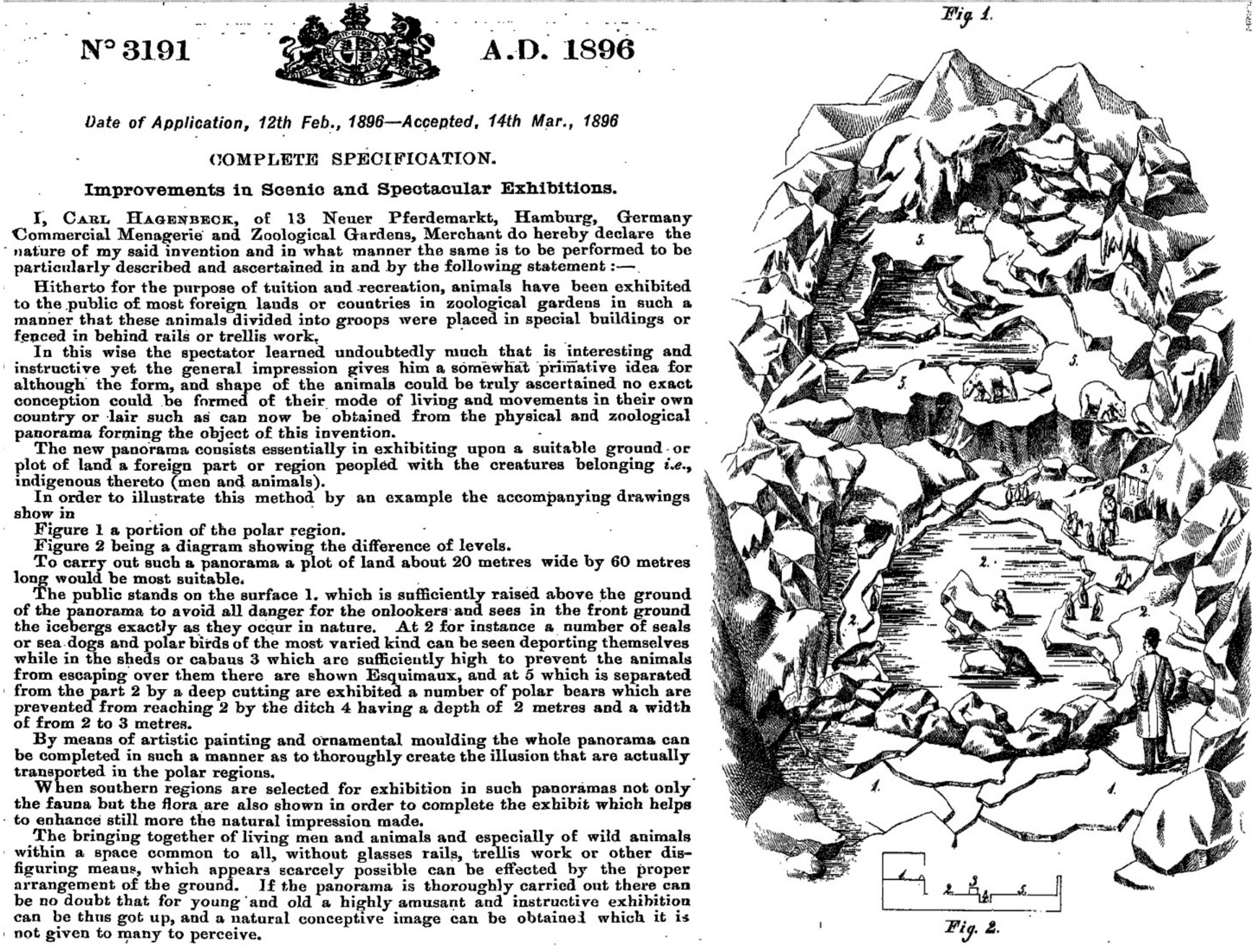
food source in relation to the sun by means of analyzing polarized, ultraviolet light from the sky, light that is invisible to us. The honeybees do not learn, either to dance or to understand the message of the dance. Both the dancing and the appropriate reactions to it are genetically programmed behavior patterns.

Konrad Lorenz has studied among many other things the fixed action patterns of various birds. His experiments with inexperienced animals, e.g. young birds from an incubator, are of great importance in this context. In these young birds he observed behavior patterns that could not reasonably have been learnt but were to be interpreted as being genetically programmed. He also found that experiences of young animals during a critical period could be decisive for their future development. Newborn ducks and geese follow the first moving object that they catch sight of, and later on they will follow those particular objects only. Normally, they will follow their mother, but they may be seduced to follow almost any moving object or creature. This phenomenon has been called 'imprinting'.

While Konrad Lorenz has above all been a systematic observer of animal behavior, Nikolaas Tinbergen has to a large extent tested various hypotheses by means of comprehensive, careful, and quite often ingenious experiments. Among other things, he has used dummies to measure the strength of different key stimuli as regards their ability to elicit corresponding fixed action patterns. He made the important observation that 'supranormal' stimuli eliciting more intense behavior than those of natural conditions, may be produced by exaggerating certain characteristics.

The discoveries made by this year's Nobel prize laureates were based on studies of insects, fishes and birds and might thus seem to be of only minor importance for human physiology or medicine. However, their discoveries have been a prerequisite for the comprehensive research that is now pursued also on mammals. Studies are devoted to the existence of genetically programmed behavior patterns, their organization, maturation and their elicitation by key stimuli. There are also studies concerning the importance of specific experiences during critical periods for the normal development of the individual. Research into the behavior of monkeys have demonstrated that serious and to a large extent lasting behavior disturbances may be the result when a baby grows up in isolation without contact with its mother and siblings or with adequate substitutes. Another important research field concerns the effects of abnormal psychosocial situations on the individual. They may lead not only to abnormal behavior but also to serious somatic illness such as arterial hypertension and myocardial infarction. One important conclusion is that the psychosocial situation of an individual cannot be too adverse to its biological equipment without serious consequences. This holds true for all species, also for that which in shameless vanity has baptized itself 'Homo sapiens'.





N° 3191 A.D. 1896

Date of Application, 12th Feb., 1896—Accepted, 14th Mar., 1896

COMPLETE SPECIFICATION.

Improvements in Scenic and Spectacular Exhibitions.

I, Carl Hagenbeck, of 13 Neuer Pferdemarkt, Hamburg, Germany Commercial Menagerie and Zoological Gardens, Merchant do hereby declare the nature of my said invention and in what manner the same is to be performed to be particularly described and ascertained in and by the following statement :—

Hitherto for the purpose of tuition and recreation, animals have been exhibited to the public of most foreign lands or countries in zoological gardens in such a manner that these animals divided into groops were placed in special buildings or fenced in behind rails or trellis work.

In this wise the spectator learned undoubtedly much that is interesting and instructive yet the general impression gives him a somewhat primative idea for although the form, and shape of the animals could be truly ascertained no exact conception could be formed of their mode of living and movements in their own country or lair such as can now be obtained from the physical and zoological panorama forming the object of this invention.

The new panorama consists essentially in exhibiting upon a suitable ground or plot of land a foreign part or region peopled with the creatures belonging *i.e.*, indigenous thereto (men and animals).

In order to illustrate this method by an example the accompanying drawings show in

Figure 1 a portion of the polar region.

Figure 2 being a diagram showing the difference of levels.

To carry out such a panorama a plot of land about 20 metres wide by 60 metres long would be most suitable.

The public stands on the surface 1. which is sufficiently raised above the ground of the panorama to avoid all danger for the onlookers and sees in the front ground the icebergs exactly as they occur in nature. At 2 for instance a number of seals or sea dogs and polar birds of the most varied kind can be seen deporting themselves while in the sheds or cabaus 3 which are sufficiently high to prevent the animals from escaping over them there are shown Esquimaux, and at 5 which is separated from the part 2 by a deep cutting are exhibited a number of polar bears which are prevented from reaching 2 by the ditch 4 having a depth of 2 metres and a width of from 2 to 3 metres.

By means of artistic painting and ornamental moulding the whole panorama can be completed in such a manner as to thoroughly create the illusion that are actually transported in the polar regions.

When southern regions are selected for exhibition in such panoramas not only the fauna but the flora are also shown in order to complete the exhibit which helps to enhance still more the natural impression made.

The bringing together of living men and animals and especially of wild animals within a space common to all, without glasses rails, trellis work or other disfiguring means, which appears scarcely possible can be effected by the proper arrangement of the ground. If the panorama is thoroughly carried out there can be no doubt that for young and old a highly amusant and instructive exhibition can be thus got up, and a natural conceptive image can be obtained which it is not given to many to perceive.

Figure 2.114: Carl Hagenbeck designed, patented, and built the first modern zoos, giving the animals much larger and much more realistic environments and separating visiting humans from the animals by height or unbridged gaps instead of bars or glass.

2.3.5 Circadian Rhythms

Scientists from the German-speaking world discovered and studied circadian rhythms, neural clocks that tell an organism what time of day to be awake, even in the absence of a visible day and night (Fig. 2.118):

- Jürgen Aschoff (German, 1913–1998) studied circadian rhythms in a wide variety of species, including humans.
- Ingeborg Beling (German, 1904–1988) discovered circadian rhythms in bees.
- Erwin Bünning (German, 1906–1990), working with Hans Kalmus, discovered circadian rhythms in fruit flies in 1935.
- Auguste Forel (Swiss, 1848–1931) discovered circadian rhythms in ants.
- Franz Halberg (Romanian/Austrian, 1919–2013) coined the term "circadian" in 1959 and studied circadian rhythms in multiple species.
- Hans Kalmus (Austrian, 1906–1988), working with Erwin Bünning, discovered circadian rhythms in fruit flies in 1935.
- Oskar Wahl (German?, 19??–19??) discovered circadian rhythms in bees.

2.3.6 Electroencephalography (EEG)

As shown in Figs. 2.119–2.120, scientists from the greater German-speaking world developed electroencephalography (EEG):

- Hans Berger (German, 1873–1941) invented electroencephalography.
- Napoleon Cybulski (Polish, 1854–1919) and Adolf Beck (Polish/Austrian, 1863–1942) also carried out early experiments in electroencephalography.
- Hans Helmut Kornhuber (1928–2009) and Lüder Deecke (1938–) discovered the Bereitschaftspotential (readiness potential) using electroencephalography.

2.3.7 Neuropathology and Neuropsychiatry

Creators from the German-speaking world made numerous and profound contributions to neuropathology and neuropsychiatry, including the discovery and diagnosis of dyslexia, autism and Asperger's syndrome, Alzheimer's disease, and other aspects (Figs. 2.121–2.123).

A. Dyslexia

The physician Adolf Kussmaul (German, 1822–1902) discovered dyslexia in 1877; he called it Wortblindheit, or word-blindness. He also demonstrated the anti-inflammatory effects of acetanilide (p. 269) and made numerous other medical discoveries (p. 401).

Apparently quite independently, another physician, Oswald Berkhan (German, 1834–1917), (re)discovered dyslexia in 1881.

Rudolf Berlin (German, 1833–1897), an ophthalmologist, coined the name dyslexia in 1887 and studied patients with the condition.

B. Autism and Asperger's syndrome

Eugen Bleuler (Swiss, 1857–1939) was a psychiatrist who studied a wide range of conditions and coined the terms schizophrenia (1908) and autism (1910). He defined autism in terms of apparent psychological withdrawal from the world.

Leo Kanner (Austrian, 1894–1981) was a psychiatrist and physician who studied and worked in Germany, then moved to the United States in the 1920s. In 1938, he began studying autistic children, and he published a detailed report on childhood autism in 1943.

Hans Asperger (Austrian, 1906–1980), a pediatric physician, diagnosed and extensively studied Asperger's syndrome and autism beginning in the 1930s. He published numerous papers on the subject from 1938 onward. Kanner and Asperger appear to have worked entirely independently; it is unclear whether one influenced the other.

C. Alzheimer's disease

Alzheimer's disease, which kills neurons and leaves protein plaques in the cerebral cortex (Fig. 2.122), was first identified in 1901 by observations of a patient with an early-onset form of the disease: Auguste Deter (German, 1850–1906).

The psychiatrists Alois Alzheimer (German, 1864–1915, after whom the disease is named) and Emil Kraepelin (German, 1856–1926) studied Deter while she was alive and discovered the protein plaques in her brain after she died.

Alzheimer also studied other dementia patients, and Kraepelin separately made important discoveries regarding manic depression and schizophrenia.

D. Other discoveries in neuropathology and neuropsychiatry

Wilhelm Erb (German, 1840–1921) made innovative discoveries related to a number of areas of neuropathology, including myasthenia gravis, progressive muscular atrophy, spinal paralysis, the effects of polio, the effects of syphilis, electrodiagnostics, and electrotherapeutics.

Edward Flatau (Polish, worked in Germany, 1868–1932) studied meningitis, migraines, and other types of neuropathologies.

Nikolaus Friedreich (German, 1825–1882) identified Friedreich's ataxia, an inherited neurodegenerative disease, in 1863.

Franz Josef Kallmann (German, 1897–1965) studied the effects of heredity vs. environment in the pathogenesis of neural diseases.

Richard Lindenberg (German, 1911–1992) was an expert on neuropathology, came to the United States as part of Operation Paperclip, and was called upon to examine the bullet wound in John F. Kennedy's head after his assassination.

Franz Nissl (German, 1860–1919) developed the Nissl staining method for labeling neurons on microscope slides in order to identify neuropathologies.

2.3.8 Psychology and Psychotherapy

Although this book does not attempt to properly cover the social sciences such as psychology (due to length constraints), it is impossible to resist mentioning at least a few of the most important German-speaking developers of psychology and psychotherapy (Figs. 2.124–2.125):

- Wilhelm Wundt (German, 1832–1920) is generally regarded as the founder of experimental psychology. He examined patients and conducted experiments in a wide variety of areas, including learning, reaction times, and sensory perception. He trained many younger experimental psychologists in his laboratory (Fig. 2.124). He also wrote a highly influential three-volume survey of physiological psychology and a ten-volume work on cultural psychology.

- Ludwig Wilhelm Stern (German, 1871–1938) devised the intelligence quotient (IQ) and also made major contributions to developmental child psychology, differential psychology, forensic psychology, and other areas.

- Josef Breuer (Austrian, 1842–1925) developed psychotherapy or the “talking cure” in the 1880s while working with his most famous patient, whom he referred to as “Anna O.” (actually Bertha Pappenheim, Austrian, 1859–1936).

- Sigmund Freud (Austrian, 1856–1939) first collaborated with and was later estranged from Joseph Breuer. He adopted the idea of psychotherapy from Breuer and greatly extended and popularized it.

- Carl Jung (Swiss, 1875–1961) initially collaborated with and later quarreled with Freud. He pursued psychotherapy but also developed his own ideas about the collective unconscious, biologically innate or culturally inspired ideas and feelings that are generally unspoken yet shared by many people within a group.

- Hermann Rorschach (Swiss, 1884–1922) combined his interests in psychiatry and art to create his now-famous inkblot test, which evaluates what subconscious ideas patients most readily identify with a series of abstract images. He wrote a textbook on psychodiagnostics and may well have achieved even more if he had not died at age 37 from a ruptured appendix.

2.3.9 Analgesics and Anesthetics

German-speaking scientists developed a wide range of neural-related drugs and treatments, including opioids, non-steroidal anti-inflammatory drugs, local and general anesthetics, barbiturates, benzodiazepines, psychoactive drugs, and electroconvulsive therapy.[21]

While the use of natural opium goes back thousands of years, opioid drug molecules were developed by German-speaking scientists in the nineteenth and early twentieth centuries (Figs. 2.126–2.127):

- Friedrich Sertürner (German states, 1783–1841) purified and identified morphine in 1804.
- Max Bockmühl (German, 1882–1949) and Gustav Ehrhart (German, 1894–1971) created methadone and over 300 other synthetic opioids.
- Heinrich Dreser (German, 1860–1924) and Felix Hoffmann (German, 1868–1946) synthesized and demonstrated heroin and codeine.

Many major non-steroidal anti-inflammatory drugs (NSAIDs) also came from German-speaking scientists (Figs. 2.127–2.129):

- Ludwig Knorr (German, 1859–1921) created an aspirin-like non-steroidal anti-inflammatory drug called phenazone in 1887.
- Friedrich Carl Duisberg (German, 1861–1935), the head of research at the Friedrich Bayer company, initiated and managed the search for fever-reducing drugs, leading to the discovery and production of aspirin in 1897.
- Arthur Eichengrün (German, 1867–1949) was in charge of the chemical synthesis group that produced aspirin, as well as a silver protein stain/antibiotic and other novel drugs.
- Felix Hoffmann (German, 1868–1946) worked with Eichengrün to synthesize aspirin and other drug molecules.
- Heinrich Dreser (German, 1860–1924) was in charge of the pharmacology testing group that demonstrated the efficacy of aspirin, codeine, and other drugs.
- Charles Frédéric Gerhardt (German states, 1816–1856) synthesized acetanilide (later known as Antifebrin) in 1843. It was derived from aniline dyes and was the first example of the class of drugs that ultimately included paracetamol (acetaminophen).
- In 1886, Adolf Kussmaul (German, 1822–1902), Arnold Cahn (German?, 18??–??), and Paul Hepp (German?, 18??–??) demonstrated the efficacy of acetanilide (Antifebrin) in humans.
- Joseph von Mering (German, 1849–1908) synthesized and demonstrated paracetamol (acetaminophen) and the closely related phenacetin (acetophenetidin) sometime prior to 1887.
- Harmon Northrop Morse (American but educated in Germany, 1848–1920) also synthesized paracetamol or acetaminophen but apparently did not pursue it further.

---

[21] Gedeon 2006; Jahn 2004; Jeffreys 2004; Junker 2004; Koesling and Schülke 2010; Kohler 2008; Magner 2002; Ohler 2017; Possehl 1989; Raviña and Kubinyi 2011; Schnalke and Atzl 2010; Schneider 1972; von Schwerin 2013; Sneader 2005; Verg 1988; Weatherall 1991.

German-speaking creators played important roles in the development of local and general anesthetics (Figs. 2.130):

- In the early 1880s, Carl Koller (Austrian, 1857–1944) tested cocaine and other substances as anesthetics for eye surgery.
- Alfred Einhorn (German, 1856–1917) developed Procaine/Novocain in 1905.
- Heinrich Braun (German, 1862–1934) also helped to develop Procaine/Novocain, as well as other local and general anesthetics in the early 1900s.

Barbiturate drugs can be used as sedatives or hypnotics for inducing relaxation or sleep, anticonvulsants for treating seizures, or general anesthetics for surgery. German-speaking creators developed and demonstrated the first barbiturates such as barbital/Veronal and phenobarbital/Luminal (Fig. 2.131):

- In 1864, Adolf von Baeyer (German, 1835–1917) synthesized barbituric acid, the parent compound of the barbiturate family.
- In 1882, Max Guthzeit (German, 1847–1915) and Max Conrad (German, 1848–1920) synthesized small quantities of barbital, a derivative of barbituric acid, but apparently did not study it further.
- Franz Joseph Emil Fischer (German, 1877–1947) and Alfred Dilthey (German, 1877–1915) synthesized large quantities of barbital in 1902 and phenobarbital in 1904.
- Joseph von Mering (German, 1849–1908) demonstrated the sedative and hypnotic effects of barbital in 1902 and phenobarbital in 1904.
- In 1912, Alfred Hauptmann (German, 1881–1948) discovered that phenobarbital could be used as an anticonvulsant to treat or prevent epileptic seizures.

[See also FIAT 914.]

In the 1950s, Leo Sternbach (Austrian, 1908–2005) developed benzodiazepine tranquilizers such as chlordiazepoxide/Librium, diazepam/Valium, flunitrazepam/Rohypnol, and many others. See Fig. 2.132.

The German-speaking world was important in the development of psychoactive drugs (Fig. 2.133):

- Albert Hofmann (Swiss, 1906–2008) synthesized lysergic acid diethylamide (LSD) in 1938 and studied its psychedelic properties in the early 1940s.
- Lazăr Edeleanu (Romanian but worked in Germany, 1861–1941) synthesized amphetamine in 1887. Methamphetamine, a more potent derivative, was packaged as Pervitin and used as a stimulant by German troops during World War II.

Creators who developed electrostimulation and electroconvulsive therapy included:

- Gustav Fritsch (German, 1838–1927, Fig. 2.104) and Eduard Hitzig (German, 1838–1907, Fig. 2.105) demonstrated the effects of electrical stimulation in the brains of dogs.
- Jacques Loeb (German, 1859–1924, Fig. 2.105) also applied electrical stimulation to localized areas of dogs' brains.
- Oskar Vogt (German, 1870–1959, Fig. 2.106) and Cécile Vogt-Mugnier (French but worked in Germany, 1875–1962, Fig. 2.106) conducted experiments to study the effects of electrostimulation of the brain.
- Walter Hess (Swiss, 1881–1973, Fig. 2.104) studied electrostimulation in the brains of cats and other subjects.
- Ladislas Meduna (Hungarian, 1896–1964, Fig. 2.134) tested metrazol and other drugs to induce convulsions in psychiatric patients for therapeutic purposes.
- Ugo Cerletti (Italian but studied in Germany, 1877–1963, Fig. 2.134) demonstrated and popularized electroconvulsive therapy.
- Friedrich Meggendorfer (German, 1880–1953, Fig. 2.134) also prominently demonstrated electroconvulsive therapy.

2.3.10 Vision

Figures 2.135–2.136 show the anatomy of the eye and the retina at the back of the eye. The retina contains three different types of cone cells to detect colored light (red, green, and blue), and also rod cells that are more sensitive but cannot distinguish colors (only black and white, but they are important for vision in dim light).

A large number of scientists from the German-speaking world made important discoveries regarding vision (Figs. 2.137–2.143).

In 1583, Felix Platter (Swiss, 1536–1614) conducted experiments on image formation with the lens of the eye.

In 1604, Johannes Kepler (Weil der Stadt, 1571–1630) provided the theoretical explanation for image formation on the retina by the lens of the eye.

In 1619, Chrisoph Scheiner (German states, 1575–1650) carried out detailed experiments demonstrating image formation on the retina by the lens of the eye.

In 1674, Antonie van Leeuwenhoek (Dutch, 1632–1723) conducted the first examination of structures in the eye with a microscope.

In his 1747 *Primae lineae physiologiae* [*Primer of Physiology*], Albrecht von Haller (Swiss, 1708–1777) proposed a general theoretical framework for how the eyes and brain process visual signals.

Johann Gottfried Zinn (German states, 1727–1759) published the first book on the detailed anatomy of the human eye, *Descriptio anatomica oculi humani* [*Anatomical Description of the Human Eye*], in 1765.

Johann Wolfgang von Goethe (German states, 1749–1832) carried out considerable experimental and theoretical work on the human perception of colors.

In 1791, Samuel Thomas von Sömmerring (German states, 1755–1830) discovered the macula lutea and the fovea in the retina.

Franz Joseph Gall (German states, 1758–1828) and Johann Spurzheim (German states, 1776–1832) described the connections from the eye to parts of the brain—the lateral geniculate nucleus and the superior colliculus in the midbrain—in 1809.

Karl Friedrich Burdach (German states, 1776–1847) studied the visual connections to the lateral geniculate nucleus and the superior colliculus in more detail in 1822.

Jakob Henle (German, 1809–1885) and Theodor Meynert (German/Austrian, 1833–1892) later confirmed the discoveries of Gall, Spurzheim, and Burdach regarding the connections to the lateral geniculate nucleus and the superior colliculus.

In the 1820s, Johann Purkinje (Austrian/Czech, 1787–1869) conducted a wide variety of experiments on vision and on factors that influence it.

In 1828, Gottfried Treviranus (German states, 1776–1837) discovered the rod photoreceptor cells in the retina.

Alfred Wilhelm Volkmann (German, 1801–1877) studied the neural connections of the visual system.

August Seebeck (German states, 1805–1849) conducted detailed studies of color blindness in 1837.

Johannes Peter Müller (German states, 1801–1858) gave a written description of the microscopic structure of the retina in 1838.

In 1839, Friedrich Heinrich Bidder (Baltic German, 1810–1894) realized that the retina is "backwards," with light having to pass through several layers of other cells to reach the photoreceptor cells.

In 1840, Heinrich Müller (German states, 1820–1864) identified the different layers of cells within the retina.

In 1851, Hermann von Helmholtz (German, 1821–1894) invented the ophthalmoscope to examine the inside of the eye; ophthalmoscopes have been widely used ever since. Von Helmholtz also conducted numerous experiments on color vision, depth perception, and motion perception. His *Handbuch der Physiologischen Optik* [*Handbook of Physiological Optics*] (1867) remained an important reference work for nearly a century.

In 1852, Rudolf Albert von Kölliker (Swiss, 1817–1905) discovered cone photoreceptor cells in the retina. Heinrich Müller confirmed that discovery in 1856.

In the 1850s, Albrecht von Gräfe (Prussian, 1828–1870) conducted detailed tests of the visual fields and described visual defects due to damage in certain parts of the brain.

In 1865, Hermann Rudolph Aubert (German, 1826–1892) published a book explaining that visual acuity and color discrimination are greatest at the center of the retina and decrease toward the edges of the retina.

In 1866, Max Schultze (German, 1825–1874) realized that cones provide color vision and rods provide black-and-white night vision.

Franz Christian Boll (German, 1849–1879) discovered rhodopsin, the light-detecting molecule in photoreceptor cells, in 1876.

In 1877, Wilhelm Kühne (German, 1837–1900) and Carl Anton Ewald (German, 1845–1915) confirmed the presence of rhodopsin in human photoreceptor cells.

Beginning in 1874, Paul Flechsig (German, 1847–1929) studied the visual processing areas of the brain.

Hermann Munk (German, 1839–1912) discovered the visual area of the occipital cortex at the back of the brain in 1878.

Hermann Wilbrand (German, 1851–1935) confirmed the location of the visual area in the occipital cortex in 1881.

August Leopold von Reuss (Austrian, 1841–1924) developed and extensively used tests for color blindness, and also measured the curvature of the cornea.

In the 1870s, Karl Ewald Hering (German, 1834–1918) proposed detailed theoretical explanations of color vision.

In 1881, Franciscus Donders (Dutch, 1818–1889) also presented a detailed explanation of color vision.

Ludwig Mauthner (Austrian, 1840–1894) made numerous contributions to knowledge about the eye, eye surgery, and the visual areas of the brain.

Constantin von Monakow (Russian, studied and worked in Switzerland, 1853–1930) conducted experimental studies of the visual areas of the brain.

In 1884, Jacques Loeb (German, 1859–1924) applied electrical stimulation to localized areas of dogs' brains to study the visual cortex.

In 1890, Adolf Beck (Polish/Austrian, 1863–1942) placed electrodes in rabbits' and dogs' brains to measure the electrical signals that were stimulated in the occipital lobe by bright lights.

Arthur König (German, 1856–1901) measured the light absorption characteristics of rhodopsin molecules in 1894.

Mieczylsław Minkowski (Polish/Swiss, 1884–1972) studied in detail the connections from the eyes to the lateral geniculate nucleus in the brain.

In the 1920s, Erwin Schrödinger (Austrian, 1887–1961) made detailed theoretical studies of color vision, including the quantum physics of the molecular detection of light of different wavelengths.

Creators who made important advances in eye surgery included (Fig. 2.144):

- Georg Beer (Austrian, 1763–1821) pioneered cataract surgery.
- Albrecht von Gräfe (Prussian, 1828–1870) developed treatments for glaucoma and cataracts.
- Carl Koller (Austrian, 1857–1944) also worked on glaucoma and cataract therapies.
- Gerhard Meyer-Schwickerath (German, 1920–1992) invented photocoagulation to treat retinal detachment.

Eye charts to measure visual acuity were developed by (Fig. 2.145):

- Heinrich Küchler (German, 1811–1873), who created the first eye charts using symbols.

- Eduard Jäger von Jaxtthal (Austrian, 1818–1884), who developed improved eye charts and also discovered diabetic retinopathy.
- Herman Snellen (Dutch, 1834–1908), who further improved and finalized eye charts.

Scientists from the greater German-speaking world also developed modern corrective lenses for vision (Fig. 2.146):

- Franciscus Donders (Dutch, 1818–1889) made the first eyeglass lenses for astigmatism in 1860.
- Adolf Gaston Eugen Fick (German, 1852–1937) invented glass contact lenses in 1888.
- Heinrich Wöhlk (German, 1913–1991) created plastic contact lenses in 1940.
- Otto Wichterle (Moravian, 1913–1998) and Drahoslav Lím (Czech, 1925–2003) developed soft contact lenses in the 1950s.

2.3.11 Hearing and Balance

As shown in Fig. 2.147, different structures in the ear provide both the sense of hearing and the sense of balance.

Hearing

Much of the earliest scientific work on ear anatomy was conducted by Italian physicians from the Renaissance and thereafter (perhaps because this area was at the intersection of Renaissance Italy's keen interests in both music and anatomy). However, later scientific work on hearing shifted steadily to the German-speaking world. Creators from the German-speaking world who made important contributions to knowledge about the sense of hearing are shown in Figs. 2.148–2.152.

In 1605, Kaspar Bauhin (Swiss, 1560–1624) proposed that varying cavity sizes within the ear could act as selective resonators to allow different parts of the ear to detect different frequencies of sound waves. That hypothesis later proved to be correct for the cochlea.

Théophile Bonet (Swiss, 1620–1689) conducted or reviewed over 3000 autopsies and reported that hearing loss could be caused by damage to small ossicles, by brain tumors, and by other factors affecting the ear and auditory parts of the brain.

Johannes Bohn (German states, 1640–1718) and Günther Christoph Schelhammer (German states, 1649–1716) separately and correctly realized that sound waves must be transferred from the air to other media in the ear in order to be detected.

Albrecht von Haller (Swiss, 1708–1777) proposed that varying cavity sizes within the cochlea in particular could act as selective resonators to allow different parts of the cochlea to detect different frequencies. He also traced the path of nerves from the ear to regions of the brain.

Rudolf Albert von Kölliker (Swiss, 1817–1905) traced nerve connections between the ear and the brain.

Heinrich Adolf Rinne (German states, 1819–1868) studied the processes by which complex sounds are detected by the ear, transmitted through nerves, and reconstructed in the brain.

Friedrich Eduard Rudolf Voltolini (German, 1819–1889) studied the responses of hair cells to sound waves of different frequencies and different amplitudes.

Hermann von Helmholtz (German, 1821–1894) conducted experimental and theoretical work to demonstrate in detail how varying cavity sizes within the cochlea could act as selective resonators to allow different parts of the cochlea to detect different frequencies.

In 1851, Ernst Heinrich Weber (German, 1795–1878) correctly analyzed, synthesized, and reported all the available information to date on how sound waves were transmitted through air, the ear drum, the ossicles, and the fluid in the cochlea in order to be detected.

Also in 1851, Ernst Reissner (Baltic German, 1824–1878) discovered the membrane in the cochlea that is now called Reissner's membrane. In addition, he studied the development of the ear in animal embryos.

In 1858, Max Schultze (German, 1825–1874) traced the auditory nerve fibers to hair cell regions of the cochlea.

Otto Friedrich Karl Deiters (German states, 1834–1863), Paul Flechsig (German, 1847–1929), Constantin von Monakow (Russian, studied and worked in Switzerland, 1853–1930), Hans Held (German, 1866–1942), and Stjepan Poljak/Stephen Polyak (Austrian/Croatian, 1889–1955) worked individually to trace in detail the nerve connections between the ear and the brain.

Christian Andreas Victor Hensen (German, 1835–1924) discovered what is now called Hensen's duct or canal in the ear. He also measured vibrations in the membrane of the cochlea.

In 1864, Adam Politzer (Austrian, 1835–1920) made automated chart recordings of vibrations in the ossicles induced by sound waves.

Ernst Mach (Austrian, 1838–1916) studied several aspects of the ear, hearing, and sound waves, including conducting experiments on how the brain can focus on particular sounds or voices out of many simultaneous ones.

Hermann Munk (German, 1839–1912) conducted experiments on the regions of the brain that analyze signals from the ears. Adolf Beck (Polish/Austrian, 1863–1942) placed electrodes in dogs' brains to measure the electrical signals that were stimulated by sounds that the dogs heard.

Carl Hasse (German, 1841–1922), Ernst Julius Richard Ewald (German, 1855–1921), and Max Friedrich Meyer (German, 1873–1967) separately conducted experiments to study how the membrane and hair cells of the cochlea detect different frequencies and amplitudes of sound waves.

Beginning in 1890, J. Habermann (German?, 18??–19??) conducted human autopsies to identify the mechanisms by which loud sounds cause hearing damage. In 1907, Karl Wittmaack (German, 1876–1972) used guinea pigs to confirm the mechanisms of hearing damage by loud sounds.

Georg von Békésy (Hungarian, 1899–1972) used strobe photography to study cochlear function in great detail. For that work, he won the Nobel Prize in Physiology or Medicine in 1961. Professor C.G. Bernhard of the Royal Caroline Institute explained von Békésy's research [https://www.nobelprize.org/prizes/medicine/1961/ceremony-speech/]:

> Von Békésy has provided us with the knowledge of the physical events at all strategically important points in the transmission system of the ear. This does not mean that the properties of the oscillating systems of the ear have not been an object of study and theoretical considerations by scientists before von Békésy. The field of physiological acoustics has a noble ancestry, in which the theories of von Helmholtz hold an authoritative position.
>
> Von Békésy's distinction is, however, to have recorded the events in this fragile biological miniature system. Authorities in this field evaluate the elaborate technique which he developed for this purpose as being worthy of a genius. By microdissection he reaches anatomical structures difficult of access, uses advanced teletechnique for stimulation and recording, and employs high magnification stroboscopic microscopy for making apparent complex membrane movements, the amplitudes of which are measured in thousandths of the millimeter.
>
> Among von Békésy's important contributions to our knowledge of sound transmission in the middle ear should be mentioned the elucidation of the vibration patterns of the eardrum and of the interplay of the ossicle movements. His technical and theoretical mastery has reached its peak in those investigations which led to the fundamental

> discoveries concerning the dynamics of the inner ear. Experimental and clinical data had confirmed von Helmholtz's assumption that the frequency of the sound waves determines the location along the basilar membrane at which stimulation occurs. The physical characteristics of the pattern of the membrane vibrations and the conditions for its appearance had, however, previously only been the object of theoretical considerations. Von Békésy succeeded in unveiling the features of the vibration pattern. He found that movements of the stirrup footplate evoke a wave complex in the basilar membrane, which travels from the stiffer basal part to the more flexible part in the apex of the cochlea. The crest of the largest wave first increases, thereafter quickly decreases. The position of the maximal amplitude was found to be dependent on the frequency of the stimulating sound waves in such a way that the highest crest of the travelling wave appears near the apex of the cochlea at low-frequency tones and near its base at high frequencies. The conditions for the appearance of these specific vibration patterns were determined in model experiments.
>
> Von Békésy then turned to the question of how the hair cells are stimulated. With a thin needle, the point of which touched the basilar membrane, different parts of the membrane could be set in vibrations in various directions. The point of the needle simultaneously served as an electrode for recording the electrical potentials from the receptor cells. It was found that a local pressure on the basilar membrane is transformed into strong shearing forces which act on the hair cells in various degrees.
>
> Thus, von Békésy has given us a clear picture of how the cochlea functions mechanically and his discoveries serve as a basis for our conception of the cochlea as a frequency analyzer.
>
> We have now reached the last strategic point of the system, that is to say the point at which the mechanical energy is transformed into the physicochemical processes which result in nerve impulses. As in the case of other sense organs, the knowledge about the electrical processes in the inner ear constitutes the foundation for further research. Von Békésy has discovered, on the one hand, the so-called endocochlear potential indicating the existence of a large potential difference over the receptor membrane at rest and, on the other hand, slow potential shifts taking place upon stimulation of the hair cells. These discoveries contribute most significantly to the analysis of the relation between the mechanical and the electrical phenomena in the receptors which are involved in the transformation of sound into nerve impulses.
>
> The work of von Békésy has greatly influenced the development of audiology and its clinical application. Thus, the development of refined diagnostic methods has made possible great advances in the treatment of diseases of the ear.

Karl Eberhard Zwicker (German, 1924–1990) investigated how the brain analyzes sounds, and he also conducted further studies of cochlear function.

German-speaking scientists also invented electric hearing aids, as shown in Fig. 2.153. Werner von Siemens invented the first (non-portable) hearing aid in 1878. At the Siemens company, Louis Weber invented the first compact portable hearing aid in 1911. The development of microelectronics by German-speaking scientists (Appendix B) ultimately allowed hearing aids to be reduced in size to fit entirely within the ear.

Balance

As shown in Fig. 2.154, major discoveries regarding the sense of balance or vestibular system were entirely dominated by creators from the German-speaking world.

In 1870, Friedrich Goltz (German, 1834–1902) discovered that the semicircular canals in the inner ear sense balance and position and transmit that information to the brain.

In 1873, Ernst Mach (Austrian, 1838–1916) and Josef Breuer (Austrian, 1842–1925), working independently of each other, both determined how fluid motion in the semicircular canals detects balance and position.

Ernst Julius Richard Ewald (German, 1855–1921) conducted experiments on the semicircular canals of pigeons to study the details of their fluid flow and detection.

Róbert Bárány (Austro-Hungarian, 1876–1936) measured the effects of temperature on fluid flow and thus sensation in the semicircular canals of human patients. For that research, he won the Nobel Prize in Physiology or Medicine in 1914. Professor G. Holmgren of the Caroline Institute praised Bárány's research as well as the earlier discoveries of Breuer and Ewald [https://www.nobelprize.org/prizes/medicine/1914/press-release/]:

> Later, a number of physiologists, especially Breuer and Ewald, studied the physiology of the inner ear and increased our knowledge of it in a high degree. Otologists also made daily observations in this field without, however, appreciating their significance and adapting them to the service of otology.
>
> After Bárány, in May 1905, had communicated his observations on caloric nystagmus to the Austrian Otological Society, there followed during the next ten years a tremendous, almost revolutionary development of otology, in which Bárány's work was both the foundation and the central theme; many other research workers also contributed, in particular the younger generation of otologists in Vienna (Alexander, Neumann, Ruttin and others).
>
> The starting-point of the work appeared, at first, to be quite simple. For a long time otologists had been aware that the syringing of a patient's ears often caused dizziness—some doctors had even observed nystagmus. But it was not known by what agency this came about or which organ released the phenomenon. Bárány made a systematic study of the question and found that syringing of the ear regularly produced nystagmus of a certain type. This nystagmus was connected with a feeling of giddiness. The explanation came to him quite by chance. A patient whose ears he was syringing said to him one day that he experienced a strong sensation of vertigo when the syringing water was too cold. Bárány then used very warm fluid in the syringe and the patient again complained of severe vertigo. Bárány noted the appearance of nystagmus here too, but its direction was the exact opposite to the one previously observed. The explanation was now clear. The decisive factor was the temperature of the syringing fluid and it was soon also clear that the phenomenon, the so-called caloric reaction, proceeded from the semi-circular canals, in which the endolymph increases in specific gravity with cooling, showing a

tendency to sink, whereas with warming the specific gravity decreases and the fluid shows a tendency to rise. The flux, or tendency to flux, which then appears in the endolymph of the semi-circular canals produces the reaction. [...]

Bárány also studied systematically the other vestibular reactions. He provided an explanation for the vestibular phenomena occurring after rotation which was in sharp contrast to what had been thought before and established the clinical and physiological importance of the so-called rotatory reaction. By means of the so-called fistula test he made the "pneumatic hammer" of the physiologist Ewald available for clinical use and he gave the galvanic reaction the secondary place which it now occupies.

He also studied the remaining phenomena of the vestibular syndrome, both the subjective and the objective ones, and systematized them. Here he was chiefly concerned with developing the question of the so-called vestibular reaction movements. First of all he established that vestibular disturbances of equilibrium, which were already known, occur in a regular manner, in a certain relationship to the existing nystagmus, so that change of position, or tendency to change of position, always occurs in the same plane but in an opposite direction to the existing nystagmus. From this follows the interesting and clinically extraordinarily important fact that existing vestibular imbalance changes direction with an alteration in the head position. These imbalances, which may stem from the muscular apparatus of the trunk, correspond with other analogous phenomena in all the other muscles which are directed by the will. With an appropriate series of experiments it can be shown how each extremity, or part of an extremity, deviates from a certain position, or tends to deviate, in the same plane but in an opposite direction to the nystagmus caused, or already present. This previously quite unknown phenomenon has become, through Bárány's so-called pointing test, an integral part of the examination methods of ear and nerve specialists.

Attempts to explain the phenomena drew Bárány in a new and promising direction leading to important investigations into the function of the cerebellum. Bárány thinks that constant impulses are going out from the cortex of the cerebellum to all the muscles controlled by the will which are thus held in a constant, and under normal circumstances, uniform state of tension (tonus). This tonus is influenced by the stimulation of the vestibular apparatus in the regular manner already indicated. If one applies the simple test (Bárány's so-called pointing test) of raising the outstretched arm from a downward position upwards opposite a suitably situated, fixed object, e.g. a graduated disc (Boivie), it will be found that with repeated attempts every normal individual reaches approximately the same spot each time with either open or closed eyes. If the same test is repeated after stimulation of the vestibular apparatus, i.e. after syringing an ear with cold or warm water, the subject will point wrongly with closed eyes and always in the same way, that is to say, in the same plane in which the nystagmus occurs, but in an opposite direction. The reaction will be the same, mutatis mutandis, if the arm is moved in the horizontal plane or if the test is made with the leg, forearm, lower leg, trunk, head, etc. Bárány has illustrated this in an excellent manner. Let us imagine a horse walking and being led by two stretched reins. The horse can be led out of its direct path either by a stronger pull on one rein or by a loosening of the other. In Bárány's pointing test the cortex of the cerebrum represents the active force—the horse—while the cerebellar cortex supplies the tonus; one must assume that it has a centre for the tonus which is directed against the sagittal axis of the body, i.e. "inwards" and also a centre for the tonus away from this axis, i.e. "outwards". When the arm is directed into the horizontal plane one must assume that, as regards tonus, it is being influenced by one centre for tonus in an upward direction and one for tonus in a downward direction. Consequently one must assume for each joint in the body the presence of four of such tonus centres in the cerebellar cortex, one for each of four possible movement directions. By close study of cases of isolated damage to the cerebellar cortex and by suitable development and adaptation of the Trendelenburg method, by which the cortical centre can be temporarily paralysed by freezing, Bárány also succeeded in establishing the presence and position of some of these centres and thereby inaugurating a kind of topical cerebellar diagnostics of a very promising nature. Although by its very nature this study presents great difficulties, the solution of which requires considerable time, many of the points raised have already been confirmed from different sources, while others must be left open.

After the outbreak of war Bárány's efforts were partly directed into other channels which must be touched upon lightly here although they are not directly within the framework of the work for which the Nobel Prize has been awarded. As a doctor in Przemysl he soon became aware that the usual methods of treating infected cranial wounds gave very unsatisfactory results. In almost all cases where projectiles had penetrated into the brain taking with them infected particles of skin and clothing, infection occurred which sooner or later led to death. Bárány assumed that the so-called open methods of treating wounds generally current at the time were directly favorable to this infection and attempted in suitable cases, after careful cleansing of the cavity, to close the wound with a primary suture, thereby preventing continuing infection from outside. With this method of treatment, which, although Bárány was unaware of it, was also beginning to be used in Germany and, particularly, in France, he obtained immediately a considerable and obvious improvement in his results and when Bárány came back in the middle of the war from a prisoner-of-war camp in Russia he applied himself exclusively to introducing the new method to the surgeons of his own country. At first he met with definite and tough resistance, but, when the experience of other countries became known and when Austrian surgeons had tried the method themselves, when also Bárány's great work on this theme was completed and published, opinion changed and he was able to add another great triumph to those previously achieved.

During the long period which he spent as a prisoner of war without any kind of literature, laboratory facilities or other scientific aids, Bárány was unable to proceed with this great work or with research into the vestibular mechanism. His speculative mind resorted then to the question of consciousness and its anatomical-physiological explanation to which he afterwards related a great part of his work, the first results of which have already been published.

2.3.12 Touch

As illustrated in Fig. 2.155, the sense of touch, or somatosensory system, employs a variety of sensory receptor cells that detect pressure, pain, heat, cold, and other stimuli. Most aspects of the somatosensory system were discovered and studied by scientists from the German-speaking world (Figs. 2.155–2.157).

In 1719, Abraham Vater (German states, 1684–1751) identified vibration- and pressure-sensitive corpuscles in the skin, later called Vater-Pacini corpuscles (after Filippo Pacini, who rediscovered them over a century later with much greater fame).

Ernst Heinrich Weber (German, 1795–1878) conducted many experiments on touch and wrote a book on touch in 1834. He developed the two-point method of determining the minimum detectable distance between touched points on different regions the body, measured the sensitivity to changes in touch pressure, and demonstrated how temperature detection interacted with other aspects of the sense of touch.

Johannes Peter Müller (German states, 1801–1858) realized that different types of nerve endings sensed different aspects of touch (pressure, heat, cold, pain, etc.), and wrote about that in his 1840 *Handbuch der Physiologie* [*Handbook of Physiology*].

Rudolf Wagner (German states, 1806–1864) analyzed the sense of touch in his 1844 *Handwörterbuch der Physiologie* [*Dictionary of Physiology*]. Along with Georg Meissner, in 1852 he also discovered Meissner's corpuscles, which detect light touch.

Hermann von Helmholtz (German, 1821–1894) measured the speed of conduction of nerve impulses related to various aspects of the sense of touch.

Moritz Schiff (German, 1823–1896) conducted experiments that differentiated between the detection of touch/pressure and pain, and also studied how those signals were transmitted through the spinal cord.

In 1852, Georg Meissner (German, 1829–1905) as well as Rudolf Wagner discovered Meissner's corpuscles, mechanoreceptors that sense light touch.

Wilhelm Wundt (German, 1832–1920) studied differences in the detection and transmission of touch sensations vs. pain.

In 1859, Wilhelm Krause (German, 1833–1910) discovered Krause's corpuscles or Krause end bulbs, which sense mechanical stimuli in mucous membranes and joints.

In 1875, Friedrich Sigmund Merkel (German, 1845–1919) discovered Merkel discs or Merkel cells, another type of mechanoreceptors that sense light touch.

Maximilian von Frey (Austrian, 1852–1932) conducted experiments to correlate different receptors with different types of touch stimuli.

Alfred Goldscheider (German, 1858–1935) determined specific locations on the skin that had receptors for heat, cold, touch, and pain.

Friedrich Kiesow (German, 1858–1940) identified regions that were sensitive to touch but not to pain.

Otfrid Foerster (German, 1873–1941) published a highly detailed map of dermatomes (regions of the skin connected to the same sensory neuron) in 1933, based on decades of experiments. He also mapped the sensory-motor regions of the cerebral cortex.

2.3.13 Taste

Scientists from the German-speaking world made important contributions to knowledge about the sense of taste or gustation (Figs. 2.158–2.160).

In his 1747 *Primae lineae physiologiae* [*Primer of Physiology*], Albrecht von Haller (Swiss, 1708–1777) classified detectable tastes into categories and proposed that they were detected by specialized structures in the tongue.

In 1752, Johann Sulzer (Swiss, 1720–1779) discovered that electricity from a primitive battery with zinc and copper electrodes could induce sensations of taste in the tongue.

Ernst Heinrich Weber (German, 1795–1878) demonstrated that temperature affects the sensitivity of the tongue to different tastes.

Johannes Peter Müller (German states, 1801–1858) discovered that different fundamental tastes can interact with each other in complex flavors.

Gabriel Valentin (German, 1810–1883) assembled and analyzed information on the sense of taste in his 1844 *Lehrbuch der Physiologie des Menschen* [*Textbook of Human Physiology*] and his 1846 *Grundriss der Physiologie des Menschen* [*Outline of Human Physiology*] .

Maximilian Ritter von Vintschgau (Austrian, 1832–1913) refined the earlier lists of tastes to the primary tastes of sour, sweet, salty, and bitter in 1880.

Wilhelm Wundt (German, 1832–1920) also classified the primary tastes in 1880.

In 1867, Gustav Schwalbe (German, 1844–1916) discovered taste buds in the tongues of humans and other mammals.

Ludimar Hermann (German, 1838–1914) studied the development of taste buds in dogs in 1884.

Napoleon Cybulski (Polish, 1854–1919) and Adolf Beck (Polish/Austrian, 1863–1942) demonstrated that different receptors in the tongue respond to different primary tastes.

Fedor Krause (German, 1857–1937) traced the nerves carrying signals from the taste buds to the brain.

In 1894, Friedrich Kiesow (German, 1858–1940) showed that the sensory reaction times of the tongue were different for the different primary tastes.

Hans Henning (German, 1885–1946) studied the fundamental tastes and their interactions.

Walter Börnstein (German, 1890–19??) discovered how the brain analyzes taste signals in 1928, and synthesized all of the accumulated data and theories on taste in 1940.

2.3.14 Smell

Scientists from the German-speaking world made important contributions to knowledge about the sense of smell or olfaction (Figs. 2.161–2.162).

Albrecht von Haller (Swiss, 1708–1777) wrote one of the earliest scientific discussions of olfaction in his 1747 *Primae lineae physiologiae* [*Primer of Physiology*] and 1757–1766 eight-volume *Elementa physiologieae* [*Elements of Physiology*].

Johannes Peter Müller (German states, 1801–1858) analyzed the scientific basis of olfaction in his 1838 *Handbuch der Physiologie des Menschen* [*Handbook of Human Physiology*].

Rudolf Wagner (German states, 1806–1864) also analyzed the scientific basis of olfaction in his 1844 *Handwörterbuch der Physiologie* [*Dictionary of Physiology*].

In 1847, Ernst Heinrich Weber (German, 1795–1878) discovered that olfaction was much more sensitive to odorant molecules dispersed in air than in water, giving important clues about the mechanism by which any olfactory receptors must operate.

Conrad Eckhard (German, 1822–1905) discovered olfactory receptor cells in the nasal epithelium of frogs in 1855.

Max Schultze (German, 1825–1874) discovered olfactory receptor cells in the nasal epithelium of humans and other mammals in 1856.

Maximilian Ritter von Vintschgau (Austrian, 1832–1913) conducted experiments to study the differences between the senses of olfaction and taste.

In 1895, Hendrik Zwaardemaker (Dutch, 1857–1930) developed a system for classifying detectable odors into categories.

In 1916, Hans Henning (German, 1885–1946) developed an alternative system for classifying detectable odors into categories.

As shown in Fig. 2.163, G. Krum (German?, 18??–19??) invented facial tissues or “paper handkerchiefs” in 1894, 30 years before the first Kleenex tissues in the United States.

KAISERLICHES PATENTAMT.

AUSGEGEBEN DEN 20. APRIL 1895.

PATENTSCHRIFT

— № 81094 —

KLASSE 30: GESUNDHEITSPFLEGE.

GÖPPINGER PAPIERFABRIK, G. KRUM IN GÖPPINGEN.

Taschentuch aus Papier.

Patentirt im Deutschen Reiche vom 14. August 1894 ab.

Der Zweck der vorliegenden Erfindung ist, den Gefahren der Uebertraguug von Krankheitskeimen (Bacterien) durch Taschentücher bei allen denjenigen ansteckenden Krankheiten, bei welchen der Ansteckungsstoff durch Einathmen übertragen wird, dadurch vorzubeugen, daſs, anstatt aus irgend einem Gewebe hergestellte Taschentücher zu benutzen, welche ihres relativ hohen Preises wegen längere Zeit hindurch wiederholt gebraucht werden, Taschentücher verwendet werden, welche man sofort nach dem Gebrauch zerstört (verbrennt oder sonstwie unschädlich macht). Diese Taschentücher sind ferner derart dicht hergestellt, daſs der aus Nase oder Mund zu entfernende Auswurf nicht hindurchdringen kann, wie dies z. B. bei den Gewebetaschentüchern der Fall ist, wo er durch die kleinen Oeffnungen der Gewebe hindurchtritt und dadurch häufig an die Hände gelangt und von denselben auf andere Stoffe oder Körpertheile übertragen wird. Weiter ist erforderlich, daſs sie billig, weich, geschmeidig und dennoch widerstandsfähig genug sind, um nicht schon bei ihrer Benutzung zerrissen oder sonst zerstört zu werden, da sonst ihre Wirkung selbstverständlich wesentlich beeinträchtigt würde.

Um alles dies zu erreichen, fertigen wir solche Taschentücher aus dünnem, der Geschmeidigkeit und Widerstandsfähigkeit halber mit Glycerin getränktem Papier an, dem eine am geeignetsten aus leichtem Verbandstoff bestehende Gewebeunterlage gegeben wird. Die Tücher können entweder unmittelbar auf der Papiermaschine hergestellt werden, indem Papier und Gewebe gemeinsam in einer Bahn durch einen mit Glycerin und Wasser gefüllten Behälter geleitet werden, oder aber es kann das in irgend einer bekannten Art mit Glycerin behandelte Papier auf das Gewebe bezw. das letztere auf das Papier aufgeleimt bezw. aufgepreſst werden. Nachträglich wird das Papier in quadratische Stücke von 15 bis 18 cm Gröſse zerschnitten und womöglich an feuchtem Orte aufbewahrt, um seine Weichheit und Geschmeidigkeit beizubehalten.

Die Kosten für den Gebrauch von derartig hergestellten kleinen Taschentüchern sind, jedesmalige Zerstörung nach Gebrauch vorausgesetzt, nicht viel gröſser, als das Waschen der seitherigen Taschentücher aus Geweben beträgt, und wird der Mehrbetrag reichlich aufgewogen durch den Schutz, den sie insbesondere in ihrer Anwendung durch mit ansteckenden Krankheiten behaftete Personen gegen weitere Uebertragung der Krankheitskeime gewähren, gleichgültig, ob letztere in der Familie oder in Krankenhäusern untergebracht sind.

PATENT-ANSPRUCH:

Für einmaligen Gebrauch mit nachträglicher Verbrennung bestimmtes Taschentuch, aus dünnem, mit Glycerin getränktem Papier bestehend, das entweder auf der Papiermaschine oder in anderer Weise mit einem dünnen Gewebeüberzug, am geeignetsten mit einem leichten Verbandstoff, durch Aufdruck oder Aufkleben versehen wird.

2.4 Cardiovascular Medicine

Scientists from the German-speaking world made many of the major discoveries and inventions in cardiovascular medicine, including:[22]

2.4.1. Hemoglobin and its properties

2.4.2. Blood pressure measurement

2.4.3. The heart-lung machine

2.4.4. Blood types and transfusions

2.4.5. Cardiovascular disease

2.4.6. Cardiovascular diagnostics

2.4.7. Cardiovascular therapeutics

2.4.8. Synthetic blood plasma

2.4.9. Transfer of cardiovascular medical innovations to other countries

2.4.1 Hemoglobin

As shown in Figs. 2.164–2.166, many scientists were involved in discovering and working out the details of how hemoglobin in red blood cells transports oxygen.

In 1840, Friedrich Ludwig Hünefeld (German, 1799–1882) discovered hemoglobin and demonstrated that it could carry oxygen.

Soon after that, in 1842, Julius Robert von Mayer (German, 1814–1878) proposed that oxidative chemical reactions provided the energy for cells throughout the body, suggesting that was the purpose of transporting oxygen through the bloodstream.

In 1851, Otto Funke (German, 1828–1879) purified hemoglobin from red blood cells and converted it into a crystalline form to measure its properties. He also investigated blood cells in the spleen.

Felix Hoppe-Seyler (German, 1825–1895) used and greatly extended Friedrich Ludwig Hünefeld's techniques to measure the binding of hemoglobin to oxygen.

Julius Lothar Meyer (German, 1830–1895) studied how carbon monoxide can displace oxygen from hemoglobin, leading to carbon monoxide poisoning. Meyer also developed and published the periodic table of the elements (p. 441).

Hans Fischer (German, 1881–1945) discovered how to chemically synthesize heme (or haemin), the iron-binding porphyrin molecule that combines with proteins to form hemoglobin. For that work, he won the 1930 Nobel Prize in Chemistry. Professor H. G. Söderbaum, Chairman of the Nobel Committee for Chemistry, described Fischer's accomplishments [https://www.nobelprize.org/prizes/chemistry/1930/ceremony-speech/]:

> This is the road which Professor Hans Fischer of Munich travelled, to reach his destination with perseverance and determination; not only did he determine completely the constitution of haemin and all its decomposition products: he also prepared the blood pigments from their simplest constituents by synthesis, a scientific achievement which would scarcely have been considered possible even a generation ago. By this synthesis he crowned his researches which both in extent and in the unbelievable difficulties associated with them deserve to be called a gigantic labour.
>
> Moreover, these researches were not wholly restricted to blood pigments. Closely related pigments occur in Nature and not only in the blood. These include the pigments in the bile, of which bilirubin is the best characterized to date. Its constitution, too, has been determined by Fischer who established the connection between this bile pigment and the blood pigment. Further, it was discovered that the pigment in the pinions of certain birds is the copper salt of a porphyrin, whereas the pigment which forms the dark spots on the eggs of a large number of wild birds, the so-called ooporphyrin, has been found to be blood pigment without iron. Even if I add that Fischer has demonstrated the occurrence of haemin in yeast, all this is overshadowed by the fact that, chemically speaking, the pigment of green plants, i.e. chlorophyll, is closely related with the red blood pigment, and even derives, as Fischer has shown, from exactly the same parent substance, as regards the porphyrins. [...]

Felix Haurowitz (Czech, 1896–1987) also made a number of structural studies and discoveries about hemoglobin and its various forms during the late 1920s and 1930s in Prague, before that research was ended by the war.

Rudolf Lemberg (German, 1896–1975) fled the Third Reich and conducted similar studies of hemoglobin in Australia in the 1930s–1950s.

Hermann Lehmann (German, 1910–1985), another refugee from the Third Reich, settled in the United Kingdom and studied hemoglobin and red blood cell abnormalities such as sickle cell anemia in the 1940s–1960s.

Max Perutz (Austrian, 1914–2002) worked out the structure of the hemoglobin protein, for which he won the 1962 Nobel Prize in Chemistry. The Royal Swedish Academy of Sciences briefly summarized his research [https://www.nobelprize.org/prizes/chemistry/1962/perutz/facts/]:

> When X-rays pass through a crystalline structure, the patterns formed can be captured as photographic images, which are then used to determine the crystal's structure. During the 1930s, this method was used to map increasingly large and complex molecules. Max Perutz began to map the structure of hemoglobin, for example—the protein that allows blood to transport energy-giving oxygen to the body's muscles. His study, completed in 1959, was later followed by further studies of the hemoglobin molecule and its function.

Werner Adolf Immerwahr (German, 1924–2006) left Germany during World War II, changed his name to Vernon Ingram, and ultimately became a well-known biology professor at MIT. With support from Max Perutz and other members of the German-speaking scientific diaspora, he spent most of his career studying the roles of proteins in diseases. In the 1950s, Immerwahr/Ingram showed that a mutation changing a single amino acid in hemoglobin was responsible for causing sickle-cell anemia, a hereditary blood disease. Later he studied some of the key proteins involved in neurodegenerative illnesses such as Alzheimer's disease.

2.4.2 Blood Pressure Measurement

As shown in Fig. 2.167, scientists from the German-speaking world created instruments for measuring blood pressure.

In 1854, Karl von Vierordt (German, 1818–1884) developed and demonstrated an instrument called a sphygmograph (somewhat like a graphing seismometer) for blood pressure measurement.

Building on the work of von Vierordt, in 1881 Samuel Siegfried von Basch (Austrian, 1837–1905) developed the more practical sphygmomanometer for blood pressure measurement.

Beginning in 1901, Heinrich Jacob von Recklinghausen (German, 1867–1942) refined von Basch's sphygmomanometer to create the modern instrument for blood pressure measurement.

2.4.3 Heart-Lung Machine

In 1885, Maximilian von Frey (Austrian, 1852–1932) and Max von Gruber (Austrian, 1853–1927) invented and demonstrated the heart-lung machine (Fig. 2.168). It could oxygenate blood and circulate that through a patient whose heart had been temporarily stopped for heart surgery. Their approach gradually spread worldwide.

The design of heart-lung machines was later improved by Willem Kolff (Dutch, 1911–2009, p. 339), who also invented renal dialysis machines.

2.4.4 Blood Types and Transfusions

Scientists from the greater German-speaking world discovered blood types and made blood transfusions safe and practical (Figs. 2.169–2.170).

Karl Landsteiner (Austrian, 1868–1943) identified blood types in 1900 and helped conduct the first matched transfusion in 1907. For that breakthrough, he won the Nobel Prize in Physiology or Medicine in 1930. Professor G. Hedrén, Chairman of the Nobel Committee for Physiology or Medicine, explained [https://www.nobelprize.org/prizes/medicine/1930/ceremony-speech/]:

> Thirty years ago, in 1900, in the course of his serological studies Landsteiner observed that when, under normal physiological conditions, blood serum of a human was added to normal blood of another human the red corpuscles in some cases coalesced into larger or smaller clusters. This observation of Landsteiner was the starting-point of his discovery of the human blood groups. In the following year, i.e. 1901, Landsteiner published his discovery that in man, blood types could be classified into three groups according to their different agglutinating properties. These agglutinating properties were identified more closely by two specific blood-cell structures, which can occur either singly or simultaneously in the same individual. A year later von Decastello and Sturli showed that there was yet another blood group. The number of blood groups in man is therefore four.
>
> Landsteiner's discovery of the blood groups was immediately confirmed but it was a long time before anyone began to realize the great importance of the discovery. The first incentive to pay greater attention to this discovery was provided by von Dungern and Hirszfeld when in 1910 they published their investigations into the hereditary transmission of blood groups.

Working independently of Landsteiner, Jan Janský (Czech/Austrian, 1873–1921) also identified and studied blood types.

In 1910, Emil von Dungern (German, 1867–1961) and Ludwik Hirszfeld (Polish, studied and worked in Germany then Switzerland, 1884–1954) discovered the heritability of ABO blood types.

Alfred Beck (German, 1889–1973) developed efficient equipment for blood transfusions.

2.4.5 Cardiovascular Disease

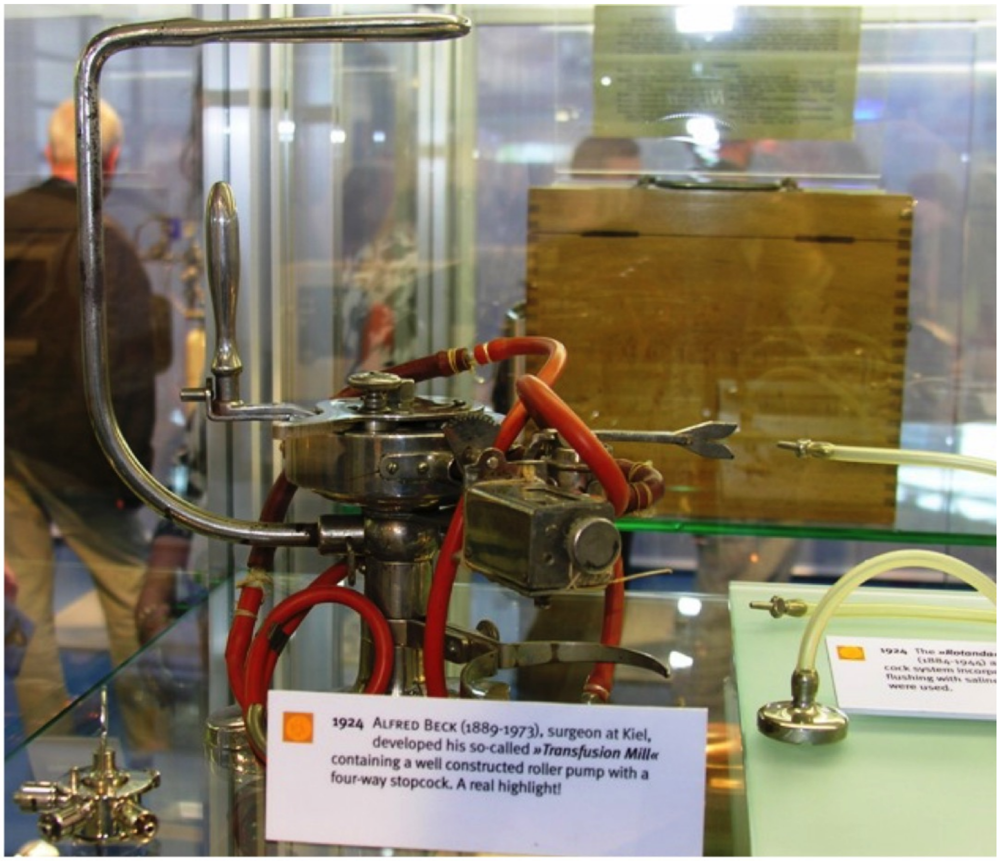
German-speaking scientists also made important contributions to knowledge about cardiovascular disease (Fig. 2.171).

Ludwig Aschoff (German, 1866–1942) identified and studied many pathophysiological conditions of the heart. His son Jürgen Aschoff conducted research on circadian rhythms (p. 258).

In 1931, Rudolf Schoenheimer (German, 1898–1941) published the results of a series of animal experiments in which he discovered and analyzed the link between dietary intake of cholesterol and atherosclerosis.

Konrad Bloch (German, 1912–2000) and Feodor Lynen (German, 1911–1979) won the Nobel Prize in Physiology or Medicine in 1964 for their work on cholesterol and fatty acid metabolism, which also had many implications for cardiovascular disease. For more information, see p. 356.

Blood transfusions



1924 Alfred Beck (1889-1973), surgeon at Kiel, developed his so-called »Transfusion Mill« containing a well constructed roller pump with a four-way stopcock. A real highlight!

	Group A	Group B	Group AB	Group O
Red blood cell type	A	B	AB	O
Antibodies in Plasma	Anti-B	Anti-A	None	Anti-A and Anti-B
Antigens in Red Blood Cell	A antigen	B antigen	A and B antigens	None

2.4.6 Cardiovascular Diagnostics

Creators from the greater German-speaking world developed the major types of cardiovascular diagnostics (Fig. 2.172).

In 1893, Wilhelm His Jr. (Swiss, 1863–1934) discovered what is now called the “bundle of His,” tissue that conducts and coordinates electrical impulses telling the heart muscle to beat.

Building on His’s discovery, in 1903, Willem Einthoven (Dutch, 1860–1927) invented the first practical electrocardiogram (ECG or EKG) for recording electrical signals from the heart. He received the Nobel Prize in Physiology or Medicine in 1924 for that work. Professor J.E. Johansson, Chairman of the Nobel Committee for Physiology or Medicine, explained Einthoven’s invention [https://www.nobelprize.org/prizes/medicine/1924/ceremony-speech/]:

> Einthoven’s name is linked partly with the design of a physical instrument, the *string galvanometer*, partly with the so-called *electrocardiogram*, a record of the electrical potential fluctuations at the surface of the body, which accompany the heart beat. The heart beat, like the piston movement of a steam engine, is a cyclic process. Behind this process lies, in the first place, a similarly cyclic process in the heart muscle.

Carl Hellmuth Hertz (German, 1920–1990), the son of Gustav Hertz (p. 893) and great nephew of Heinrich Hertz (p. 854), developed echocardiography, which uses ultrasonic waves and acoustic signal recording and imaging methods to analyze heart function. He obtained the first echocardiogram in 1953, and later he also developed inkjet printing.

See also p. 1250 for the early development of ultrasound imaging by the German-speaking world.

2.4.7 Cardiovascular Therapeutics

Scientists from the greater German-speaking world also developed many important cardiovascular therapeutics, including both devices and medications (Fig. 2.173).

In 1929, Werner Forßmann (German, 1904–1979) invented and successfully demonstrated the cardiac catheter. For that revolutionary innovation, he won the Nobel Prize in Physiology or Medicine in 1956. Professor G. Liljestrand, Secretary of the Nobel Committee for Physiology or Medicine, praised his work [https://www.nobelprize.org/prizes/medicine/1956/ceremony-speech/]:

> As far as man is concerned, these methods were for a long time only partly applicable. Thus, it was possible to record the pressure in the peripheral arteries—and this is what is usually meant when we speak of the blood pressure—as well as in the superficial veins. These values reflect to some extent the conditions in the left ventricle and the right atrium. But measurements of the right ventricular pressure, which is of essential importance for the work of the right side of the heart, was impracticable. Similarly, it was possible, for determination of the oxygen content, to take samples of the arterial blood, but not of the mixed venous blood in the right side of the heart, which gives the average value for the body as a whole. It was, in fact, necessary to resort to indirect methods. These have yielded valuable results, although they have somewhat undeservedly—as is often the case—been overshadowed by the subsequent conquests. One of the factors limiting the applicability of these indirect methods was, however, that they required the active cooperation of the experimental subject or patient, and this was at times associated with difficulties or was altogether unfeasible.
>
> As late as 1928, there were good reasons for the statement in a textbook that in man, one was "naturally" confined to the use of the indirect methods. Consequently, it was highly surprising when, already in the following year, Werner Forssmann at the surgical clinic in Eberswalde was able to show—by making, with the intrepidity of youth, by no means harmless experiments on himself—that a narrow catheter could be advanced from a cubital vein into the right atrium itself, a distance of almost two-thirds of a metre. Obviously, this constituted a remarkable advance.

Willem Kolff (Dutch, 1911–2009) invented, developed, and successfully demonstrated the renal dialysis machine during World War II. After the war, his technology rapidly spread around the world, and Kolff moved to the United States, where he continued to develop improved dialysis machines, as well as improved heart-lung machines.

Arthur Stoll (Swiss, 1887–1971) led a research team at Sandoz in Basel that developed some of the earliest and most important heart medications, including cardiac glycosides, alkaloids, and soluble calcium salts.

German-speaking scientists developed early blood pressure medications such as adrenochrome (p. 340) and pentaerythritol tetranitrate (PETN, p. 535). After World War II, those discoveries were adopted by other countries [e.g., CIOS ER 115–116]. Much more archival research should be conducted to elucidate the history of the development of blood pressure medications in the German-speaking world, along with the direct and indirect effects that knowledge had on drug development in other countries.

2.4.8 Synthetic Blood Plasma

As shown in Figs. 2.174–2.176, by the early 1940s, at least two synthetic blood plasma substitutes were developed and successfully tested in the German-speaking world [Brinkman et al. 1945; Hüsselmann 1952; Schoen 1949; NYT 1945-09-21 p. 5, 1947-05-25 p. 42, 1951-02-08 p. 35, 1951-05-20 p. E9]. This work was decades ahead of its time, since perfecting synthetic blood substitutes for battlefield use is still a subject of great military and medical interest.

Periston was developed and tested by Walter Reppe (German, 1892–1969, see p. 474), Hellmut Weese (German, 1897–1954), and G. Hecht (German?, 18??–19??). It was a saline-glucose solution containing completely synthetic polymers of polyvinyl pyrrolidone suspended as a colloid. Periston was far more than a laboratory experiment—it was successfully employed in hundreds of thousands of patients in wartime and early postwar Germany, due to the very large numbers of patients and the shortage of real human blood plasma. The *New York Times* reported the history and successes of periston [NYT 1951-05-20]:

> Confronted in 1939 with a serious shortage of blood, the German Government encouraged Drs. G. Hecht and H. Weese, among others, to develop a blood plasma substitute. Hecht and Weese rejected gum solutions and sought instead a colloid which would not slip easily through the membranes of the kidneys, as salt solutions do, and which would readily absorb water. The quest ended with a product which was christened "Periston" and which is chemically called polyvinyl pyrrolidon.
>
> This polyvinyl pyrrolidon is an artificial compound synthesized from acetylene, ammonia and formaldehyde. The molecule so obtained is coupled with others, a process called polymerization, which means coupling of small molecules to form big ones. Rubber is a polymer, and so is many a synthetic fiber. Since polymers are big molecules, they are not easily lost by slipping through membranes of the kidneys and out of the blood stream.
>
> Periston or PVP, as it was also known, was used successfully during the recent war in the treatment of 500,000 German battlefront casualties. Since the war the preparation has been widely used in Germany in surgical clinics because there is still a shortage of blood for transfusions.

Another synthetic blood plasma was capain, which was a saline solution containing polypeptide fragments that had been hydrolyzed from casein (purified milk protein), as well as glucose and other ingredients. It was also manufactured on a commercial scale and used successfully in humans (pp. 76 and 342).

2.4.9 Transfer of Cardiovascular Medical Innovations to Other Countries

Many innovations in cardiovascular medicine—such as blood pressure measurement, the heart-lung machine, blood type matching, and the electrocardiogram—were rapidly adopted worldwide after they were invented or discovered by scientists in the German-speaking world in the late nineteenth and early twentieth centuries.

All of the remaining innovations in cardiovascular medicine were transferred from the German-speaking world to other countries after World War II. For examples see Fig. 2.174 and FIAT 779, *Work on Physiology of the Circulatory System and on Electrophysiology.*

BENEFITING OUR ECONOMY AND SECURITY

AND WITH PROMISING POTENTIALITIES

Periston, a blood substitute used in transfusions, promises to take an important place in medical practice in cases of loss of blood from injuries, surgical operations, and birth hemorrhages, in shock, in cholera and sprue where blood volume is dangerously lowered, and in a variety of cases where whole blood of any proper type is indicated but is not immediately available. Developed by I. G. Farbenindustrie research, Periston represents a balanced mixture of a new colloid (kollidon) and appropriate mineral salts, prepared to simulate and assume the normal carrier functions of human blood plasma. It is inexpensive, easily stored in any climate, ready for immediate emergency use, and compatible with all blood types. Periston is being evaluated by the American Medical Association and the National Institute of Health. The German records show its use in 300,000 transfusions in 40,000 patients, with the claim of saving thousands of lives.

Adrenochrome, a derivative of adrenalin, has been prepared by German chemists in a purer state, stabile in dry form in ampules. It has been recommended as a convenient adjunct for treatment of diabetes, since it can be administered orally and it is claimed that it reduces the amount of necessary insulin injections to one-half. It is also claimed that it reduces high blood-pressure, a disease which American physicians state kills three quarters of a million people annually in the United States alone. In view of these recommendations, American pharmaceutical firms are beginning to manufacture this product, and the National Institute of Health is pursuing research on it.

Rutenol, a new German pharmaceutical product of the I. G. Farbenindustrie, is being currently studied and tested at the Army Medical College and the National Institute of Health, since it is claimed as a marked improvement over the well-known and effective nitroacridine from which it was derived by the addition of arsenic trioxide. This is a more promising one of a whole series of German arsenical pharmaceuticals pointed at combatting all richettsia

organisms which are responsible for spotted fever and scrub typhus. It is also claimed to be effective in dysentery of bacillary or amoebic origins. While new and perhaps inadequately tested by German clinicians, enough present evidence demands thorough-going research and clinical evaluation since these infections are always widely potential in the U.S.A.

Figure 2.174: The German-speaking world developed a variety of medicines and medical products that were transferred to other countries after World War II, as shown for example by this document [NARA RG 40, Entry UD-75, Box 58, Folder TIID Discards].

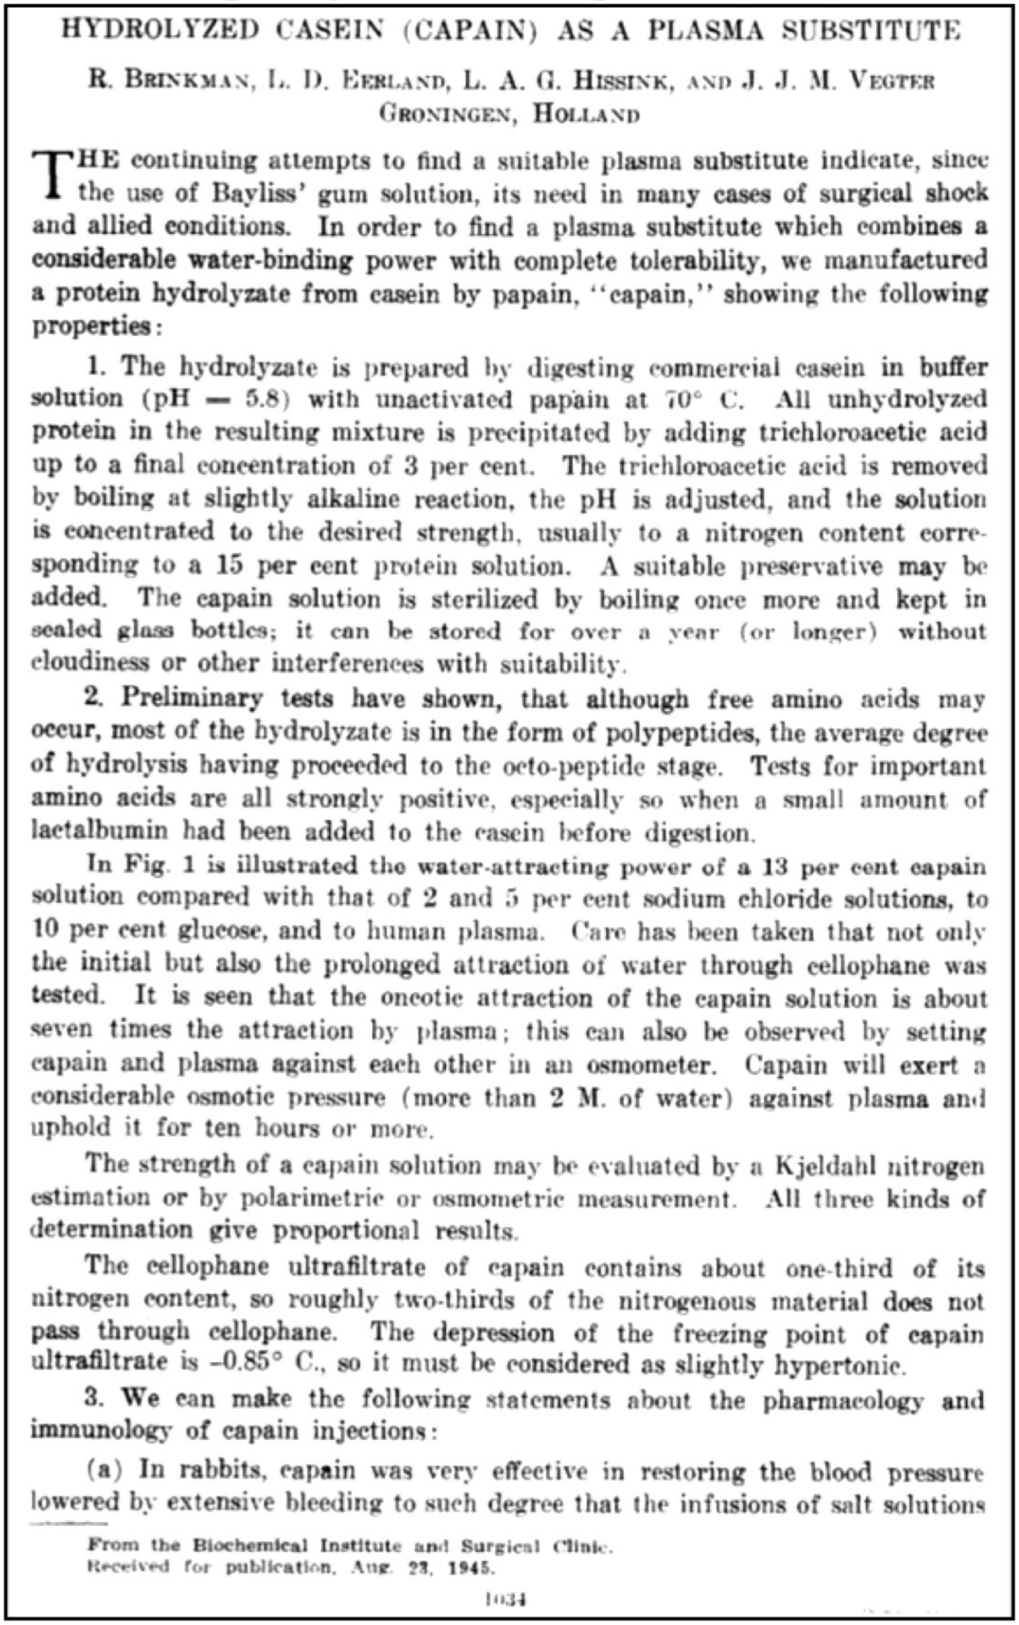
Capain synthetic blood plasma (1943)



HYDROLYZED CASEIN (CAPAIN) AS A PLASMA SUBSTITUTE

R. Brinkman, L. D. Eerland, L. A. G. Hissink, and J. J. M. Vegter
Groningen, Holland

The continuing attempts to find a suitable plasma substitute indicate, since the use of Bayliss' gum solution, its need in many cases of surgical shock and allied conditions. In order to find a plasma substitute which combines a considerable water-binding power with complete tolerability, we manufactured a protein hydrolyzate from casein by papain, "capain," showing the following properties:

1. The hydrolyzate is prepared by digesting commercial casein in buffer solution (pH — 5.8) with unactivated papain at 70° C. All unhydrolyzed protein in the resulting mixture is precipitated by adding trichloroacetic acid up to a final concentration of 3 per cent. The trichloroacetic acid is removed by boiling at slightly alkaline reaction, the pH is adjusted, and the solution is concentrated to the desired strength, usually to a nitrogen content corresponding to a 15 per cent protein solution. A suitable preservative may be added. The capain solution is sterilized by boiling once more and kept in sealed glass bottles; it can be stored for over a year (or longer) without cloudiness or other interferences with suitability.

2. Preliminary tests have shown, that although free amino acids may occur, most of the hydrolyzate is in the form of polypeptides, the average degree of hydrolysis having proceeded to the octo-peptide stage. Tests for important amino acids are all strongly positive, especially so when a small amount of lactalbumin had been added to the casein before digestion.

In Fig. 1 is illustrated the water-attracting power of a 13 per cent capain solution compared with that of 2 and 5 per cent sodium chloride solutions, to 10 per cent glucose, and to human plasma. Care has been taken that not only the initial but also the prolonged attraction of water through cellophane was tested. It is seen that the oncotic attraction of the capain solution is about seven times the attraction by plasma; this can also be observed by setting capain and plasma against each other in an osmometer. Capain will exert a considerable osmotic pressure (more than 2 M. of water) against plasma and uphold it for ten hours or more.

The strength of a capain solution may be evaluated by a Kjeldahl nitrogen estimation or by polarimetric or osmometric measurement. All three kinds of determination give proportional results.

The cellophane ultrafiltrate of capain contains about one-third of its nitrogen content, so roughly two-thirds of the nitrogenous material does not pass through cellophane. The depression of the freezing point of capain ultrafiltrate is –0.85° C., so it must be considered as slightly hypertonic.

3. We can make the following statements about the pharmacology and immunology of capain injections:

(a) In rabbits, capain was very effective in restoring the blood pressure lowered by extensive bleeding to such degree that the infusions of salt solutions

---

Figure 2.176: Creators from the German-speaking world also developed and successfully used capain as a synthetic blood plasma substitute.

2.5 Vitamins and Hormones

Vitamins are essential biochemical molecules that the human body needs yet cannot make for itself (at least in sufficient quantities), so they must be acquired from foods or other sources. Hormones are biochemical molecules that cells in the body use to send various signals to each other; many belong to the family of steroid hormones derived from cholesterol, but other hormones do not. There are a number of biochemical connections between vitamin molecules and hormone molecules, and hence there was considerable overlap in these research areas. Creators from the greater German-speaking world made many major discoveries and innovations regarding:

2.5.1. Vitamins

2.5.2. Steroid hormones

2.5.3. Nonsteroidal hormones

2.5.1 Vitamins

It is helpful to cover the basics of vitamin molecules, in order to better understand the importance of the original discoveries and scientific studies of those vitamins. Vitamins may be divided into those that are hydrophobic (do not like to be in water) and therefore fat-soluble, and those that are hydrophilic (like to be in water) and therefore water-soluble.

Fat-soluble vitamins can accumulate in body fat and are difficult to dissolve in water and eliminate in urine. Thus they can last a long time in the body, but they can also have toxic effects if they are consumed in excess. As shown in Fig. 2.177, some major fat-soluble vitamins include:

- Vitamin A (retinol) can be derived from certain plants such as carrots, sweet potato, pumpkin, spinach, kale, etc., or fats from animals that have previously ingested such plants. Retinol and its related forms are essential components of light-detecting rhodopsin molecules in the eye and of some DNA-regulating transcription factors in cell nuclei. Too little vitamin A can cause blindness and sterility; too much can cause liver damage or birth defects.

- Vitamin D (cholecalciferol) can be made from cholesterol in human skin exposed to enough sunlight; otherwise it can be derived from certain mushrooms, alfalfa, or animals that have previously ingested such foods. Vitamin D acts on the intestine and bones to maintain sufficient levels of calcium and phosphorus. Insufficient vitamin D can cause bone demineralization and deformation (rickets). Excessive vitamin D can cause nausea or kidney stones.

- Vitamin E (tocopherol) is found in vegetable oils, which are used to make many foods. It acts as an antioxidant to prevent oxidative damage to cells, so its absence can increase oxidative damage, especially in red blood cells that carry lots of oxygen and in neurons that use lots of oxygen. Too much vitamin E can interfere with proper blood clotting.

- Vitamin K (phylloquinone) can be derived from leafy green vegetables such as spinach, collard greens, broccoli, and Brussels sprouts. Vitamin K is also made by the bacteria that naturally live inside the gastrointestinal tract. Vitamin K is used as a coenzyme to modify a number of human proteins, most of which play key roles in blood clotting. Too little vitamin K can hinder blood clotting, and too much can potentially harm red blood cells.

Water-soluble vitamins are not stored in body fat and are readily eliminated in urine. As a result, one can quickly become deficient in these vitamins if they are not consumed regularly, yet it is difficult to overdose on them. Water-soluble vitamins are especially important for the synthesis of biomolecules such as amino acids and nucleotides, and for metabolism to produce energy by breaking down fats and sugars. Thus the effects of water-soluble vitamin deficiencies are most pronounced in rapidly dividing cells that need lots of biomolecular synthesis and energetic metabolism (e.g., blood-cell-producing bone marrow, mucous membrane and skin cells, and developing embryos), and in neurons in the central or peripheral nervous system that are damaged if their steady energetic metabolism is interrupted. As shown in Fig. 2.178, some major water-soluble vitamins include:

- Vitamin B_1 (thiamine) can be derived from whole grains, legumes, nuts, or fungi, or from products (e.g., liver, eggs) from animals that have consumed those foods. It is a precursor for thiamine pyrophosphate, which prepares sugars for the energy-producing citric acid cycle. Thiamine deficiency can damage the central nervous system, a condition called beriberi.
- Vitamin B_2 (riboflavin) is found in leafy vegetables, legumes, and products (milk, eggs, liver) from animals that have consumed those foods. Cells use it to produce two major electron and proton transport proteins.
- Vitamin B_3 (niacin) can be derived from grains, cereal, nuts, milk, and meat. It is an essential precursor of two other electron and proton transport proteins.
- Vitamin B_5 (pantothenic acid) is found in a very wide variety of plant- and animal-derived foods and is a component of coenzyme A, which carries several molecules through metabolic pathways.
- Vitamin B_6 (pyridoxine) is also found in a wide range of plant- and animal-derived foods, and is a precursor of pyridoxal 5'-phosphate, a cofactor for a number of metabolic reactions.
- Vitamin B_7 or H (biotin) is found in a great variety of plant- and animal-derived foods and is also produced by bacteria in the human intestine, so biotin deficiency is virtually unheard of. Biotin is an important cofactor or component of several different carboxylase enzymes.
- Vitamin B_9 or M (folic acid or folate) is most plentiful in leafy green vegetables. It is a precursor of tetrahydrofolate, a coenzyme essential for amino acid and nucleotide synthesis.
- Vitamin C (ascorbic acid) is abundant in most fruits. It is an essential cofactor for a number of enzymes, including those involved in collagen synthesis, and may play a role as an antioxidant to prevent cellular damage from free oxygen radicals.

Because there are such profound human health implications from having too little or too much of a given vitamin, the discoveries of individual vitamins and their properties were major milestones in biology and medicine, and many of those discoveries were recognized with Nobel Prizes. Figures 2.179–2.180 show some scientists who made important discoveries about vitamins.[23]

Vitamin B$_6$ (pyridoxine)
Vitamin B$_7$ or H (biotin)
Vitamin B$_9$ or M (folic acid)
Vitamin C (ascorbic acid)

Figure 2.178: Some major water-soluble vitamins include vitamins B$_1$ (thiamine), B$_2$ (riboflavin), B$_3$ (niacin), B$_5$ (pantothenic acid), B$_6$ (pyridoxine), B$_7$ or H (biotin), B$_9$ or M (folic acid), and C (ascorbic acid).

Christiaan Eijkman (Dutch, 1858–1930) discovered vitamin B_1 and its importance for preventing beriberi. For that discovery, he won the Nobel Prize in Physiology or Medicine in 1929. Professor G. Liljestrand, a member of the Royal Caroline Institute, described Eijkman's discovery and its implications [https://www.nobelprize.org/prizes/medicine/1929/ceremony-speech/]:

> It was the analysis of the nature of the food used in cases of polyneuritis in hens that led Eijkman to his discovery. As a rule, analysis and synthesis complete each other, and indeed the employment of both these avenues of approach has been of decisive importance also for the development of the science of vitamins. [...]
>
> Many years have passed, since Eijkman found the antineuritic principle in food, but the great importance of this work has been appreciated but slowly. Today, however, the outstanding significance of the discovery is universally acknowledged not only for our understanding and our attempt to combat beriberi, but also because it has indicated a way of investigating and controlling many other deficiency diseases.

Albert Eschenmoser (Swiss, 1925–) artificially synthesized vitamin B_{12}, the vitamin with the most complex molecular structure. Eschenmoser also developed methods of synthesizing artificial nucleic acids that differ from natural DNA and RNA.

Casimir (Kazimierz) Funk (Polish, educated in Switzerland and worked in Germany before moving to United States, 1884–1967) first coined the word "vitamin" (or "vital amine") and helped to identify the molecular structures and/or dietary effects of vitamins B_1, B_2, B_3, C, and D. He also did important early work on steroid hormones. Despite his many important discoveries regarding vitamins and hormones, he never won a Nobel Prize.

Paul Karrer (Swiss, 1889–1971) conducted research that helped to identify vitamins A, B_2, C, and E. He won the Nobel Prize in Chemistry in 1937. Professor W. Palmær, Chairman of the Nobel Committee for Chemistry, stated [https://www.nobelprize.org/prizes/chemistry/1937/ceremony-speech/]:

> The Royal Academy of Sciences has decided also to award to Professor Paul Karrer in Zurich one half of the Nobel Prize in Chemistry this year in recognition of his researches concerning carotenoids and flavins, and the vitamins A and B_2. [...]
>
> Karrer has thus succeeded in elucidating completely the nature of two of the vitamins, hitherto considered as so mysterious, and one of them is now produced artificially. A characteristic of this scientist is his open eye to the great and important problems as well as to their kernels, and the independent way in which he attacks the problems and pursues his new departures with the aid of his own methods.

Richard Kuhn (Austrian, 1900–1967) made major discoveries regarding the chemical structures and synthesis of vitamins A, B_2, and B_6, for which he won the Nobel Prize in Chemistry in 1938. He also synthesized antibiotics (p. 190) and nerve agents (p. 585) and conducted a wide variety of other innovative biochemical work during his career. The Royal Swedish Academy of Sciences described Kuhn's vitamin discoveries [https://www.nobelprize.org/prizes/chemistry/1938/kuhn/facts/]:

> Kuhn investigated theoretical problems of organic chemistry (stereochemistry of aliphatic and aromatic compounds; syntheses of polyenes and cumulenes; constitution and colour; the acidity of hydrocarbons), as well as extensive fields in biochemistry (carotenoids; flavins; vitamins and enzymes).

> For a period of twenty years Kuhn investigated compounds containing double bonds which proved to be of great interest in connection with the study of the chemical nature of the carotenoids. He discovered eight new types of these and was able to analyse their constitution. He also carried out important work on vitamin B2 and the antidermatitis vitamin B6. For his work in this important field Kuhn was awarded the Nobel Prize for Chemistry in 1938.

Feodor Lynen (German, 1911–1979) made important discoveries regarding vitamin B_7, cholesterol, and fatty acid metabolism. He won the Nobel Prize in Physiology or Medicine in 1964. His work regarding cholesterol and hormones is discussed on p. 356.

Tadeusz Reichstein (Polish, educated and worked in Switzerland, 1897–1996) discovered a method to synthesize vitamin C that is now called the Reichstein process and is still widely used. He won the Nobel Prize in Physiology or Medicine in 1950 for his research on cortisone (p. 356).

Albert Szent-Györgyi (Hungarian, 1893–1986) was the first to purify vitamin C, and he also made important discoveries regarding other vitamins, muscle metabolism, and the Krebs cycle. He won the Nobel Prize in Physiology or Medicine in 1937. Professor E. Hammarsten, a member of the Royal Caroline Institute, explained the importance of Szent-Györgyi's work on vitamin C and other vitamins [https://www.nobelprize.org/prizes/medicine/1937/ceremony-speech/]:

> The magnificent series of Szent-Györgyi's discoveries commenced in 1933. They were carried out and pursued at Szeged with extraordinary rapidity and precision. His clear vision for essentials induced him, in spite of his isolation of ascorbic acid and of his identification of it with the so-termed vitamin C—a feat that was justly hailed with enthusiasm—to hand over to others for the time being the tempting pursuit of the further development of that discovery, and to devote the whole of his energy to the problem of combustion, notwithstanding the difficulties it presented. [...]
>
> It is of especially great importance that at least two vitamins—C and B_2, and possibly B_1, and P—are in cooperation in the oxidation chain and are catalysts, illustrating the way in which these vitamins act in the organism.

Adolf Windaus (German, 1876–1959) made important discoveries regarding the structures and synthesis of vitamin D and cholesterol, for which he won the Nobel Prize in Chemistry in 1928. Professor H. G. Söderbaum, Secretary of the Royal Swedish Academy of Sciences, discussed Windaus's discoveries [https://www.nobelprize.org/prizes/chemistry/1928/ceremony-speech/]:

> Another sterol which Windaus has studied in detail, is ergosterol, which occurs partly in ergot and partly in yeast. The research carried out in recent years, in which Windaus himself has also played a leading part, has revealed the very important fact that, on being irradiated with ultraviolet light, this ergosterol assumes exactly the same properties as the antirachitic vitamin, "vitamin D", i.e. it will cure rachitis (rickets). For example, it has been found that 5 mg of irradiated ergosterol has the same action in this respect as 1 litre of good cod-liver oil. It can be considered proved, therefore, that ergosterol, or possibly a sterol, the physiological effects of which correspond completely with those of ergosterol, constitutes the antirachitic provitamin, i.e. the mother substance of vitamin D. [...] For there is no doubt that your work on sterols, vegetable cardiac poisons and other closely related substances merits in the same high degree such an award as the work which we have just recognized.

2.5.2 Steroid Hormones

Many hormones belong to the family of steroid hormones; several examples are shown in Fig. 2.181. Steroid hormones are all derived from cholesterol. Various steroid hormones are produced by certain organs, pass through the bloodstream, and enter target cells elsewhere in the body to deliver their signals. The best-known steroid hormones are the male hormone testosterone, produced by the testes, and female hormones progesterone and estradiol (estrogen), produced by the ovaries. However, the large family of steroid hormones also includes non-sexual hormones, such as cortisone, an anti-inflammatory hormone produced by the adrenal glands in response to stress, and aldosterone, produced by the adrenal glands to regulate blood pressure.

Both the natural science and the practical applications of steroid hormones were developed almost entirely by creators from the greater German-speaking world.[24] Figures 2.182–2.191 show some of the key individuals who were involved. The discoveries regarding these hormones had revolutionary, immediate, and long-lasting implications, making possible the creation of:

- Pregnancy tests
- Hormonal contraceptives
- Menopause treatments
- Anabolic steroids
- Anti-inflammatory steroid drugs
- Blood pressure medications
- Therapeutics for high cholesterol
- Etc.

Arnold Adolph Berthold (German states, 1803–1861) demonstrated the existence of sexual hormones by removing the testes from roosters and then successfully re-implanting them in other regions of some of the birds, showing that the testes produced substances that passed through the blood to affect sexual characteristics.

Austrian gynecologists Rudolf Chrobak (1843–1910) and Emil Knauer (1867–1935) built upon that work, as reported by professor of pharmacology Walter Sneader [Sneader 2005, p. 173]:

---

[24] Butenandt 1931; Dominguez-Lacasa 2005; Gausemeier 2005; Jahn 2004; Junker 2004; Karlson 1990; Koesling and Schülke 2010; Kohler 2008; Magner 2002; Marks 2010; Possehl 1989; Raviña and Kubinyi 2011; Schieder and Trunk 2004; Schneider 1972; von Schwerin 2013; Sneader 2005; Stoff 2012; Taschwer 2016; Weatherall 1991.

> During the period of enthusiasm for organotherapy at the end of the nineteenth century, the Viennese gynaecologist Rudolf Chrobak gave tablets prepared from cows' ovaries to his patients in an attempt to overcome the undesirable effects that ensued after surgical removal of their ovaries. Chrobak then asked his assistant, Emil Knauer, to investigate the effects of transplantation of ovarian tissue in animals. He began by extirpating the ovaries of rabbits and showing that this led to involution of the uterus and cessation of the oestrus cycles. However, when he reimplanted the ovaries elsewhere in the animals, normal ovarian function was restored. His work inspired others to administer desiccated ovaries or extracts of these to patients in the hope of relieving menopausal disorders.

In 1912, Eugen Steinach (Austrian, 1861–1944) went further than the same-sex experiments of Berthold and Knauer. He demonstrated that transplanting the testes from male to female guinea pigs caused the female guinea pigs to develop male characteristics.

Heinrich Wieland (German, 1877–1957) won the 1927 Nobel Prize in Chemistry for his research on the biochemical synthesis of bile acids, which are chemically related to cholesterol and therefore shed knowledge on this whole family of molecules. Professor H. G. Söderbaum, Secretary of the Royal Swedish Academy of Sciences, summarized the methods and the importance of Wieland's research [https://www.nobelprize.org/prizes/chemistry/1927/ceremony-speech/]:

> Wieland succeeded in producing from bile a saturated acid which can be regarded as the mother substance or parent acid of the bile acids, and which he studied and characterized in detail. When Windaus then produced this same parent acid, cholanic acid, from cholesterol by means of a complicated and very ingenious series of experiments, this indicated very clearly the close relationship between cholesterol and the bile acids. It should be pointed out in this connection that Wieland's investigations into bile acids themselves gave a deeper insight of the mechanism of the action of the bile in the resorption of food in the intestines. [...]
>
> Professor Wieland. The decision of the Royal Academy of Sciences to award you the Nobel Prize in Chemistry for your work on bile acids and related substances, is only a just recognition of the solution of a problem which is without doubt one of the most difficult which organic chemistry has had to tackle.
>
> The complex composition of the compounds investigated, the large number of atoms contained in the molecules of these compounds, the fact that the material was often very difficult to produce, even in small quantities, these were obstacles which could only be overcome with such striking success through a remarkable skill in experimentation and a rare capacity for finding new ways and means.

During the 1930s, four different groups working in parallel within the German-speaking world almost simultaneously purified, identified, and chemically synthesized the various male and female sexual hormones:

1. In Germany, Adolf Butenandt (German, 1903–1995) purified and identified several natural sex hormones in the 1930s [Butenandt 1931; Karlson 1990; Schieder and Trunk 2004]. He won the 1939 Nobel Prize in Chemistry for that work. The Royal Swedish Academy of Sciences emphasized the significance of the research of Butenandt and his collaborators [https://www.nobelprize.org/prizes/chemistry/1939/butenandt/facts/]:

> Hormones are substances that transfer signals between the body's cells and organs and regulate bodily functions. In the 1930s Adolf Butenandt contributed to the mapping of several hormones that specifically apply to men and women, respectively. After determining the composition of the female sex hormone estrogen, he was able to determine the structure for this hormone and a related hormone, estriol. He was also able to produce a male sex hormone in pure form for the first time and to determine its chemical composition. It was named androsterone.

Butenandt worked at several universities and then became head of the Kaiser Wilhelm Institute for Biochemistry. During that time, he worked with a team of other hormone experts in his academic laboratories, including Hans Dannenbaum (German?, 18??–19??), Günther Hanisch (German?, 18??–19??), Helmut Kudszus (German?, 18??–19??), and Kurt Tscherning (German?, 18??–19??). Butenandt also worked closely with the Schering pharmaceutical company to commercialize production of both naturally derived and chemically synthesized hormones for a variety of purposes (Figs. 2.183–2.186). Some especially noteworthy scientists at Schering included:

- Max Dohrn (German, 1874–1943, chemist) who worked on everything from sex hormones to insulin to sulfonamide antibiotics.

- Fritz Hildebrandt (German, 1887–1961, pharmacologist).

- Walter Hohlweg (Austrian, 1902–1992, endocrinologist) and Hans-Herloff Inhoffen (German, 1906–1992, Schering chemist), who developed an orally effective form of estrogen. Inhoffen also chemically synthesized vitamins A and D.

- Carl Kaufmann (German, 1900–1980, gynecologist), who worked on female sexual hormones and their relevance for treating menstrual disorders and cancers.

- Johannes Schultze (German?, ??–??, chemist), an expert on the chemical synthesis of steroid hormones.

- Erwin Schwenk (Austrian, 1887–1976, chemist), who moved to Schering's U.S. branch and set up similar work there.

2. In Switzerland, Leopold Ružička (Austro-Hungarian/Croatian, studied in Germany and worked in Switzerland, 1887–1976) chemically synthesized sex hormones in the 1930s. For that work, he also won the 1939 Nobel Prize in Chemistry. The Royal Swedish Academy of Sciences summarized the results of Ružička and his collaborators [https://www.nobelprize.org/prizes/chemistry/1939/ruzicka/facts/]:

> Terpenes are a large and varied group of substances that range from rubber and the solvent turpentine to the cholesterol in our blood. Leopold Ruzicka studied fragrances in perfumes and became interested in how they were related to other substances. In the mid-1920s he came to the conclusion that the substances were composed of the same building block, terpene isoprene. By manipulating cholesterol molecules, Leopold Ruzicka succeeded in producing the male sex hormone androsterone and later demonstrated that testosterone also could be produced from cholesterol.

Just as Butenandt collaborated with the German pharmaceutical company Schering, Ružička collaborated with the Swiss pharmaceutical company CIBA (Chemische Industrie Basel) [Ratmoko 2010]. Chemists at Ciba who were especially important for steroid hormone synthesis included Max Hartmann (Swiss, 1884–1952), Karl Miescher (Swiss, 1892–1974), Ernst Tschopp (Swiss?, ??–19??), and Albert Wettstein (Swiss, 1907–1974). See Fig. 2.187.

3. At the University of Vienna, the chemist Karl Slotta (German, 1895–1987) led a group that also included gynecologist Erich Fels (German, 1897–1981) and chemist Heinrich Ruschig (German, 1906–1994); see Fig. 2.188. They too were at the forefront of discovering, synthesizing, and testing various steroid hormones.

4. At the University of Amsterdam and the collaborating Organon pharmaceutical company, physician Ernst Laqueur (German, 1880–1947) led a group that also included Kåroly Gyula David (Hungarian, 1905–1945, killed in the Gusen concentration camp), Elisabeth Dingemanse (Dutch, 1886–1952), John (Johann) Freud (Hungarian, ??–??), Bernard Josephy (German, 18??–19??), and Otto Mühlbock (German, 1906–1979) [Oudshoorn 1991], as shown in Fig. 2.189. They published numerous papers and patented a variety of hormonal compounds, running neck-and-neck with the German, Swiss, and Austrian groups.

In 1927, the gynecologists Selmar Aschheim (German, 1878–1965) and Bernhard Zondek (German, 1891–1966) developed the first pregnancy test, measuring hormone changes in urine with the onset of pregnancy [Sneader 2005, p. 174]. The test involved injecting a woman's urine into an immature female mouse (Fig. 2.190). If the woman was not pregnant, no changes were noted in the mouse. If the woman was pregnant, the mouse visibly went into heat from the extra hormones, even though it was not mature enough to produce its own hormones. This test was adopted worldwide (often with rabbits instead of mice) and used for decades until it was replaced by *in vitro* immunoassays (which had also been invented by German-speaking scientists—see p. 228). This test detected human chorionic gonadotropin (hCG), which Aschheim and Zondek also purified and identified. While hCG is a protein hormone and not a steroid, its function is directly tied to steroid hormones, so it is included in this section.

Based on the latest discoveries about female sexual hormones, Ludwig Haberlandt (Austrian, 1885–1932) proposed hormonal birth control in 1921, successfully demonstrated it in animals during the 1920s, and tried to initiate human trials beginning in 1930 (Fig. 2.191). Although Haberlandt's hormonal contraceptive was never officially approved for that purpose in humans, it appears to have unofficially achieved considerable use from the 1930s onward. Historian Lara Marks recounted Haberlandt's struggles and achievements [Marks 2010, pp. 47–48]:

> [H]e had successfully conducted a series of animal experiments by 1927, proving the contraceptive value of ovarian and placental extracts. By the late 1920s he was negotiating with the German-based pharmaceutical firms E. Merck and I. G. Farben to produce a progesterone-based hormonal contraceptive. Neither of these companies, however, were willing to take on the project. Despite the increasing use of contraception among couples in these years, research into contraception remained highly taboo. Haberlandt himself was denied promotion in his own academic institution because of the hostility of the Catholic lobby to his contraceptive work. Despite these difficulties, in 1928 Haberlandt secured an agreement to develop his hormonal contraceptive with Gedeon Richter, a Hungarian company producing hormones, based in Budapest. By 1930 the company

> had commercially registered a compound called Infecundin. Haberlandt faced problems getting the product tested on humans because he was not a clinician. Although he approached a number of physicians to try out the drug as a hormonal contraceptive in women, no one was willing to support it.
>
> Though Haberlandt himself died prematurely in 1932, his product was tested at a women's hospital in Innsbruck in 1934. The results of this research were never published. The drug, however, had its commercial registration renewed in 1940 and 1950. Infecundin, or a similar substance called Profecundin, is also rumoured to have been promoted in Germany during 1942. [...I]n 1966 Gedeon Richter, by then a state-owned company, promoted Infecundin as the first Hungarian contraceptive pill.

Carl Djerassi (Austrian/Bulgarian, 1923–2015), having trained in the German-speaking world, studied the details of Haberlandt's work, and worked with other German-speaking pioneers from the early days of hormone research, proceeded to commercialize hormonal birth control in Mexico and the United States in the 1950s. Lara Marks described direct links between Djerassi and the earlier work by Haberlandt and other German-speaking hormone researchers [Marks 2010, pp. 67–68]:

> [...] Emerik Somlo [...] had started off his career in Mexico in 1928 as a representative for the Hungarian company Gedeon Richter, which at that time was negotiating its agreement with Haberlandt in Europe to produce an oral contraceptive. In Mexico Somlo had established a lucrative trade for Gedeon Richter due to the almost total absence of other drug houses. He soon realized he could push the business even further with the establishment of a laboratory within Mexico. Refused funding by Gedeon Richter to finance such a project, Somlo collaborated with a young German Jewish chemist, Frederico Lehmann, to set up the laboratory and their own company, Laboratorios Hormona, in 1933. Much of the production of this firm was built up through the expertise of refugee European scientists recruited to the company in the 1930s. Feeling the ravages of fascism, these scientists brought with them many of the advances in hormone knowledge and production in Europe in the interwar period. [...]
>
> In 1945 Somlo hired a Hungarian Jewish chemist, George Rosenkrantz [at Somlo and Lehman's new company Syntex...] Trained in technical sciences and chemical engineering at the Eidgenossische Technische Hochschule (Technical School of the Confederation) in Zurich in the 1930s, Rosenkrantz had worked alongside leading experts in the chemical synthesis of male hormones. His supervisor, Leopold Ruzicka, for instance, had received the Nobel Prize in 1939 as a result of his work on male hormones with Adolf Butenandt, one of the discoverers of oestrone. [...]
>
> In 1948, Rosenkrantz was joined in these efforts by a young American (born in Vienna), the Jewish Carl Djerassi. Recruite together with a number of other scientists, some of whom had trained with Rosenkrantz in Zurich, Djerassi had a strong background in steroidal chemistry. After leaving Europe in 1938, he had obtained a doctorate from the University of Wisconsin in 1945. His graduate work had focused on the chemical conversion of the male hormone, testosterone, into the female hormone, oestrogen. Djerassi subsequently worked for the American subsidiary of the Swiss company CIBA, which held the patent for cholesterol, whence he joined Syntex. Employed by Syntex as part of its drive to fulfill its industrial potential and expand its range of steroidal intermedi-

> aries, Djerassi not only brought with him industrial expertise and a knowledge of steroid chemistry, but also a desire to establish an academic and scientific reputation.

Marks also noted [Marks 2010, p. 11]:

> In a recent paper Djerassi calls himself 'The mother of the pill'. Such mythology partly stems from the fact that much of the early history of the oral contraceptive was written by the scientists and medical experts involved in its initial development, who had an interest in promoting themselves as its inventors.

Tadeusz Reichstein (Polish, educated and worked in Switzerland, 1897–1996) won the Nobel Prize in Physiology or Medicine in 1950 for identifying cortisone, a steroid hormone that is not sex-related, but rather produced in response to stress. Professor G. Liljestrand of the Royal Caroline Institute announced the award [https://www.nobelprize.org/prizes/medicine/1950/ceremony-speech/]:

> Professor Tadeus Reichstein. To you and your co-workers we owe the first isolation of four active hormones from the adrenal cortex, the first synthesis of one of them, the proof of the steroid nature of said hormones, and numerous details on the structure and properties of these important bodies. In this way the wearisome road to synthesis was smoothed, and new medicaments created. Your discoveries in this field are of fundamental importance.

Konrad Bloch (German, 1912–2000) and Feodor Lynen (German, 1911–1979) won the Nobel Prize in Physiology or Medicine in 1964 for their work on cholesterol and fatty acid metabolism, which also had many implications for the biochemistry of hormones. Professor S. Bergström of the Nobel Committee for Physiology or Medicine explained some of their research [https://www.nobelprize.org/prizes/medicine/1964/ceremony-speech/]:

> At an early stage Bloch made another discovery of fundamental importance in showing that cholesterol is the precursor of bile acids and of one of the female sex hormones. These discoveries opened up a new field of research that has engaged a great number of scientists in different disciplines. We know now that all substances of steroid nature in our body are formed from cholesterol.
>
> Mainly through the basic biochemical work of this year's prizewinners do we know today in detail how cholesterol and fatty acids are synthesized and metabolized in the body. These processes comprise series of reactions with a great number of individual steps. For instance, the formation of cholesterol from acetic acid is a process involving some thirty different steps. Derangements of this complicated mechanism of formation and metabolism of lipids are in many cases responsible for the genesis of some of our most important diseases, especially in the cardiovascular field. A detailed knowledge of the mechanisms of lipid metabolism is necessary to deal with these medical problems in a rational manner.
>
> The importance of the work of Bloch and Lynen lies in the fact that we now know the reactions which have to be studied in relation to inherited and other factors. We can now predict that we, through further research in this field in the near future, can expect to be able to do individual specific therapy against the diseases that in the developed countries are the most common cause of death.

Carl Djerassi (shown with a student) commercialized a version of Haberlandt's oral contraceptive in North America in the 1950s and achieved much greater fame.

2.5.3 Nonsteroidal Hormones

Creators from the greater German-speaking world also made many major discoveries about nonsteroidal hormones, such as thyroid hormone, adrenaline, and insulin.[25] For closely related work on neurotransmitters, see p. 245.

Some important scientists who studied thyroid hormone production are shown in Fig. 2.192.

Theodor Billroth (Prussian/Austrian, 1829–1894) pioneered a wide variety of surgical techniques in the neck, including the thyroid, and the abdomen. Even the American Council of Learned Societies deemed his work especially noteworthy, well over a century later [ACLS 2000, p. 99]:

> Billroth, the son of a clergyman, took a doctorate in medicine at Berlin (1952) and directed the surgical clinic at Zurich (1860–67) and the University of Vienna (to 1894). [...] His *Die allgemeine chirurgische Pathologie und Chirurgie in fünfzig Vorlesungen* (1863) is a classic surgical textbook. He helped introduce antisepsis on the Continent, and was the first to resect the esophagus (1872), to perform total laryngectomy (1873), and to resect a cancerous pylorus (1881). His methods of resection, although modified, remained in use for many years. Plastic surgery, especially of the face, was another of his specialties. His pupils spread his teaching all over the Continent.

One of Billroth's students, Emil Theodor Kocher (Swiss, 1841–1917), greatly expanded on his initial work and elucidated the principles of thyroid disease and successful treatment. For these achievements, Kocher won the 1909 Nobel Prize in Physiology or Medicine. Professor the Count K. A. H. Mörner, Rector of the Royal Caroline Institute emphasized the importance of Kocher's work [https://www.nobelprize.org/prizes/medicine/1909/ceremony-speech/]:

> Not only the thyroid, but also various other glands such as the adrenals and the pancreas play a characteristic part in the processes within the organism by elaborating a secretion peculiar to each gland, which is not excreted, but is diffused throughout the organism and is of the greatest importance to it. [...]
>
> However, it is not only the treatment of the goitre which has been the subject of Kocher's research on the goitre. He has also carried out extensive investigations into the causes of the endemic occurrence of goitre in certain regions and into the cretinism connected with disturbances in thyroid function.
>
> In the thyroid, as already indicated, other diseases can occur in addition to those which arise with the ordinary goitre. To these as well Kocher has devoted successful work, as a result of which it has been possible to define with more and more certainty the method of treatment best suited to each case; in addition, on the basis of Kocher's work a broader, deeper knowledge of the pathology of the thyroid has been achieved.

Eugen Baumann (German, 1846–1896) demonstrated that thyroxine was the hormone produced by the thyroid gland.

Scientists who made major discoveries about the hormone adrenaline or epinephrine are shown in Fig. 2.193:

- In 1895, Napoleon Cybulski (Polish, 1854–1919) and his student Władysław Szymonowicz (Polish, 1869–1939) first isolated and identified adrenaline.
- Otto von Fürth (Austrian, 1867–1938) independently purified adrenaline in 1898.
- In 1899, Max Lewandowsky (German, 1876–1916) showed that injecting adrenaline extract into animals immediately elicited strong responses from nerves and muscles.
- Friedrich Stolz (German, 1860–1936) first used chemical methods to synthesize adrenaline in 1904.
- Ernst Joseph Friedmann (German, 1877–1956) worked out the molecular structure of adrenaline in 1906.

Another important hormone is insulin. Glucose, a simple form of sugar, is circulated through the blood to feed cells in the body, but too much glucose can actually damage cells, a condition called diabetes. Part of the pancreas monitors the level of glucose in the blood and, when necessary, sends out insulin to tell other organs to lower the amount of glucose. Thus the discovery of insulin had enormous implications both for understanding the cause of diabetes and for successfully treating it.

As shown in Figs. 2.194–2.195, German-speaking scientists made virtually all of the key discoveries regarding the role of insulin in controlling and preventing diabetes.[26]

In 1869, Paul Langerhans (German, 1847–1888) discovered the clumps of cells in the pancreas that produce insulin, which are now called the islets of Langerhans.

Joseph von Mering (German, 1849–1908) and Oskar Minkowski (Baltic German, studied and worked in Germany, 1858–1931) demonstrated in 1889 that surgically removing the pancreas of a dog caused diabetes, and therefore that a product of the pancreas was essential for controlling and preventing diabetes. (Josef von Mering also helped to discover barbiturates—see p. 277).

Georg Ludwig Zülzer (German, 1870–1949), working together with Max Dohrn (German, 1874–1943, a prolific chemist who also helped to synthesize steroid hormones and antibiotics) and Anton Marxer (German, 1880–19??) at Schering, conducted the first experiments demonstrating that insulin could be purified from calf pancreas (in an extract called Acomatol) and used to treat diabetic symptoms, beginning in rabbits in 1903 and humans in 1906 [Mellinghoff 1971, 1972]. Their first insulin preparations demonstrably worked to control the symptoms of diabetes in humans, but they also produced some inflammatory reactions due to the presence of impurities from animal pancreas remaining in the preparations.

Zülzer and his colleagues continued working steadily to improve their insulin production process in order to eliminate any remaining impurities. They were on the verge of achieving a marketable final product, yet unfortunately their experiments were terminated in 1914 when medical personnel and facilities were conscripted into caring for soldiers wounded in World War I. With the four years of war, followed immediately by years of crippling national reparations payments and economic depression, Zülzer was unable to renew his experiments.

---

[26] Bliss 2007, pp. 25–31; Meienhofer 1963; Mellinghoff 1971, 1972; von Schwerin et al. 2013, pp. 151–155; Sneader 2005, pp. 164–166.

Erich Leschke (German, 1887–1933) also developed and demonstrated injectable forms of insulin purified from animal pancreases, producing a doctoral thesis on the topic in 1911 (*Über die Wirkung des Pankreasextraktes auf pankreasdiabetische und auf normale Tiere*, or *On the Effect of Pancreatic Extract on Pancreatic-Diabetic and Normal Animals*).

By closely following the steps of the insulin purification process that were described in detail in Zülzer's published papers and patents, Frederick Banting (Canadian, 1891–1941) and John Macleod (Scottish, 1876–1935) replicated his work and used Zülzer's own methods to eliminate any remaining impurities in insulin in 1922. They were awarded the Nobel Prize in Physiology or Medicine the very next year, in 1923, and have been lauded in the history books ever since. Zülzer has been all but forgotten.

It seems quite likely that if World War I had not intervened, Zülzer (and perhaps Dohrn, Marxer, or Leschke) would have won the Nobel Prize for that achievement. In any event, without all of the discoveries from Langerhans, von Mering, Minkowski, Zülzer, Dohrn, Marxer, Leschke, and other scientists in the German-speaking world who labored for half a century to go from discovering insulin to purifying it, the now-widespread use of insulin to treat diabetes would have begun far later than it did.

To avoid the necessity of purifying natural insulin from animals, Helmut Zahn (German, 1916–2004) at Aachen University began working on methods of artificially synthesizing insulin after World War II, based on protein synthesis techniques that had been pioneered in 1932 by Max Bergmann (German, 1886–1944, p. 130). Zahn and his coworkers successfully produced and demonstrated the first synthetic insulin in 1963 [Meienhofer 1963]. (By using Bergmann's methods, the University of Pittsburgh also produced synthetic insulin somewhat later.) That synthetic insulin was also the first application of an artificially created protein, a major milestone in biotechnology. All of the insulin used worldwide is now produced by biotechnological processes.

2.6 Developmental Biology and Embryology

Creators from the German-speaking world pioneered developmental biology (Section 2.6.1), as well as techniques to aid childbirth and neonatal babies (Section 2.6.2).

2.6.1 Developmental Biology

Developmental biology is the study of how a fertilized egg cell multiplies and becomes the many highly specialized and highly organized cells of a whole organism (Figs. 2.196–2.197). Scientists from the greater German-speaking world virtually monopolized the field of developmental biology and embryology for more than a century.[27] In awarding the 1935 Nobel Prize in Physiology or Medicine to Hans Spemann, Professor G. Häggquist of the Royal Caroline Institute emphasized how completely it was German-speaking scientists who had created and who continued to dominate the field of developmental biology [https://www.nobelprize.org/prizes/medicine/1935/ceremony-speech/]:

> Developmental mechanics seeks to establish the inner causal connection between the developmental processes. Wilhelm Roux founded this branch of science at the end of the 80's of the last century. Although Roux himself, Driesch, and many others have enriched our knowledge with interesting facts, it was really Spemann and his school who first established developmental mechanics as a current branch of science which has revealed laws and relationships which encompass the entire biological world.
>
> In his technical work, Spemann can be called a micro-surgeon. His instruments are simple: glass rods drawn to a point, glass tubes which can be used as fine pipettes, or loops of children's hair. His experimental material consisted of the eggs of newts and frogs. An egg cell of this kind is a little ball of living matter with a diameter of 1–1.5 mm. Normally after fertilization it develops by continued segmentation until it changes into a small hollow sphere whose wall consists of small cells. Subsequently this hollow sphere invaginates rather as if you were to take a burst rubber ball and squeeze it together in the hand; only the difference is that the walls grow together so that the orifice of the now double-walled sphere will be small and cleftshaped. After that, a further layer of cells grows between the two walls of the sphere. These three layers are called *ectoderm*, *mesoderm*, and *endoderm* from outside inwards respectively. The orifice is called the *blastopore*. Then in front of this blastopore there arise from the ectoderm the primordia of the brain and spinal cord. Beneath the primordial brain an invagination of the ectoderm against the entoderm is formed, later to become the mouth. The mesoderm will form the skeleton (in the first place the dorsal strip, then the notochord) and muscles. The endoderm forms gut.
>
> Much thought has been given to the nature of the forces and causality regulating this development. It is at this point that Spemann's researches begin. He used eggs of various animal species which differ in colour, and with his simple instruments transplanted small pieces of tissue in different stages of development. [...]

> [...] Spemann has revealed conditions in the developmental process which are of deep significance. A mountain of difficulties rears up before him who seeks to wrest from Nature, secrets connected with the origin and development of a new individual. Spemann has opened this mountain and has brought to light rich treasures of knowledge. Moreover, a group of disciples has followed him, who can carry his thoughts forward and continue the work at such time as the master himself grows weary. [...]
>
> Herr Geheimrat [Spemann]. You are a student of Theodor Boveri, and occupy the Chair once held by Professor August Weismann. These are two names of vast reputation evoking feelings of gratitude and admiration in anyone engaged in biological research. They are, however, also names imposing on the student and successor responsibilities for carrying on a great tradition. You, Herr Geheimrat, have been successful in upholding this proud scientific tradition. You have, with new tools, continued where Weismann and Boveri had to stop, and have paved new ways in biology. August Weismann managed, although ignorant of Mendel's observations, to outline the significance of the nucleus as bearer of heredity; Boveri laid, together with Oscar Hertwig, the foundation of our knowledge of the fertilization phenomena; and you, Herr Geheimrat, have discovered secret forces regulating the early development of the fertilized egg. You have also created a school of scientists from whom Science can expect further valuable contributions. As a result of this you have occupied a place in the first rank of great cultural personalities in which your country is so rich.

Figures 2.198–2.202 show some of the most important scientists in developmental biology. Their research methods and results were so complex, and there was so much overlap in their careers and their discoveries, that these creators are simply mentioned in alphabetical order here. For much more detail on all of these scientists and their research, please see the cited references.

Karl Ernst von Baer (Baltic German, 1792–1876) discovered the early blastula stage of development, studied the germ layers (ectoderm, mesoderm, and endoderm) of the following gastrula stage in a variety of vertebrates, and discovered the notochord (the early developmental stage of the spinal column).

Carl Bergmann (German states, 1814–1865) studied comparative anatomy and formulated what is now called "Bergmann's rule"—the observation that species generally tend to be larger in colder climates and smaller in warmer climates.

Theodor Boveri (German, 1862–1915) showed that chromosomes carry the inherited traits of an organism, and that proper embyonic development requires the normal number of chromosomes for an organism.

Hans Driesch (German, 1867–1941) demonstrated that embryonic cells in the early blastula stage are totipotent and can become any part of the resulting animal, or completely separate animals if they are split apart and allowed to resume development. In a sense, Driesch's successful experiments splitting apart the cells of one developing embryo to create many identical embryos were the earliest demonstration of cloning.

Karl Gegenbaur (German, 1826–1903) was one of the pioneers of comparative anatomy and developmental morphology, and published highly influential textbooks showing the evolutionary relationships among structures in different species.

Salome Gluecksohn-Waelsch (German, 1907–2007) was the founder of developmental genetics, the study of how specific genes influence the development of an embryo and the differentiation of initially totipotent cells into highly specialized cell types committed to different fates.

Ernst Haeckel (German, 1834–1919) was a student of Karl Gegenbaur, and also conducted extensive studies in comparative embryology among a variety of species.

Curt Herbst (German, 1866–1946) demonstrated the importance of ion concentrations for differentiation and development in embryos.

Oscar Hertwig (German, 1849–1922) stated in 1885 that nucleic acid (DNA) is responsible for inherited characteristics, meticulously documented cellular events during fertilization, and made other contributions to developmental biology. He was the older brother of Richard Hertwig.

Richard Hertwig (German, 1850–1937) was the younger brother of Oscar Hertwig, and he also elucidated the process of fertilization and conducted other studies in developmental biology.

Wilhelm His Sr. (Swiss, 1831–1904) documented the development of the central and peripheral nervous system, described endothelial tissue layers, and (along with Johann Purkinje, p. 78) was one of the inventors of the microtome, which has become a widely used instrument for preparing thin slices of animal or plant tissues for microscope slides. He was the father of Wilhelm His Jr. (p. 335).

Johannes Holtfreter (German, 1901–1992) conducted a long series of experiments demonstrating how organizer or inducer regions of an embryo produce chemical gradients that control the body plan or location and layout of organs.

Johann Friedrich Wilhelm Krause (German, 1833–1910) made a variety of contributions to developmental biology and human anatomy, including studies of the peripheral nervous system.

Hilde Mangold (German, 1898–1924) made discoveries that led to a Nobel Prize (for her supervisor Hans Spemann in 1935), although unfortunately she did not live to share in that award. Developmental biologists Scott Gilbert and Michael Barresi briefly recounted her story [Gilbert and Barresi 2016, p. 347]:

> The most spectacular transplantation experiments were published by Spemann and his doctoral student Hilde Mangold in 1924. They showed that, of all the tissues in the early gastrula, only one has its fate autonomously determined. This self-determining tissue is the dorsal lip of the blastopore—the tissue derived from the gray crescent cytoplasm opposite the point of sperm entry. When this tissue was transplanted into the presumptive belly skin region of another gastrula, it not only continued to be dorsal blastopore lip but also initiated gastrulation and embryogenesis in the surrounding tissue! [...]
>
> Hilde Proescholdt Mangold died in a tragic accident in 1924, when her kitchen's gasoline

> heater exploded. She has 26 years old, and her paper was just about to be published. Hers is one of the very few doctoral theses in biology that have directly resulted in the awarding of a Nobel Prize.

Otto Mangold (German, 1891–1962), the husband of Hilde Mangold, also made important contributions to developmental biology, especially with regard to the differentiation of initially totipotent embryonic cells into highly specialized, committed cell types.

Johann Friedrich Meckel (Prussian Saxony, 1781–1833) was one of the first scientists to make a systematic study of birth defects and abnormalities that occur during the development of an embryo.

Heinz (or Heinrich) Christian Pander (Baltic German, 1794–1865) discovered and studied the three germ layers (ectoderm, mesoderm, and endoderm) in chick embryos.

Martin Heinrich Rathke (German states, 1793–1860) carefully studied the developmental biology of a wide variety of vertebrate and invertebrate species, and was the first to identify many features in their development.

Karl Bogislaus Reichert (German, 1811–1883) investigated and reported on the development of a number of different structures in vertebrate embryos.

Robert Remak (Prussian, 1815–1865) studied and described in detail the three germ layers (ectoderm, mesoderm, and endoderm) of the gastrula.

Wilhelm Roux (German, 1850–1924) conducted experiments on the development of the skeletal and cardiovascular systems in vertebrate embryos.

Hans Spemann (German, 1869–1941) worked with Hilde Mangold and others on a wide range of topics in developmental biology. For experiments that Hilde Mangold carried out, Spemann won the Nobel Prize in Physiology or Medicine in 1935 (p. 375). In 1936, Spemann published *Experimentelle Beiträge zu einer Theorie der Entwicklung* (translated into English in 1938 as *Embryonic Development and Induction*), a book that included a detailed and scientifically accurate description of experimental methods for cloning adult animals by removing the nucleus of an egg cell and replacing it with the nucleus from a cell of an adult to be cloned. It is not clear how far experiments with that approach actually progressed in Germany before the end of World War II; much more archival research should be performed to investigate that matter. In any event, Spemann's approach was successfully used by other scientists to create cloned animals in the decades after the war.

Walther (or Walter) Vogt (German, 1888–1941) was the first to use a vital (nontoxic) dye for fate mapping of cells in developing embryos, in order to determine which types of cells arise from a particular earlier cell that was injected with the tracking dye.

Heinrich Wilhelm von Waldeyer-Hartz (German, 1836–1921) discovered the developmental stages for many structures in the head, including teeth, tonsils, and hair.

Else Wehmeier (German?, 19??–??) conducted important experiments demonstrating the action of organizer or inducer regions in an embryo.

August Weismann (German, 1834–1914) studied reproduction and development in sea urchins as a very simple animal model, and made many important contributions regarding chromosomes and heredity.

Paul Alfred Weiss (Austrian, 1898–1989) studied cellular differentiation and tissue regeneration in cultured cells and in whole amphibians.

Caspar Friedrich Wolff (Brandenburg, 1733–1794) founded the fields of animal and plant developmental biology. He studied plant, chick, human, and other embryos and made important discoveries regarding early developmental stages, developmental abnormalities, and the development of organ systems such as the gastrointestinal tract.

Although it was somewhat later than the primary time period covered by this book, Christiane Nüsslein-Volhard (German, 1942–) and Eric Wieschaus (U.S. but worked in Germany, 1947–) studied the genetic control of embryonic development. For that work, they won the Nobel Prize in Physiology or Medicine in 1995. Professor Björn Vennström of the Nobel Committee at the Karolinska Institute explained their discoveries [https://www.nobelprize.org/prizes/medicine/1995/ceremony-speech/]:

> Insect larvae have segments; recall the larva of a butterfly! Each segment has its own developmental program. Think about the wasp, with its head, the central section, and the striped posterior ("tail") region: every part develops from a specific segment in the larva. Christiane Nüsslein-Volhard and Eric Wieschaus decided to find all the genes that cause the larva to develop exactly 14 segments, since the segments determine the body plan. Their chances of success were unclear. Nobody had done anything similar before, and a hopelessly large number of genes could be involved. They began their work, using a simple but ingenious experimental approach. After having tested more than half of the approximately 20000 genes of the fly, they found three groups of genes that govern segmentation. The first group of genes provides a basis for segmentation along the body axis. The next group of genes governs the development of every second segment, whereas the third group refines the structure of the individual segments.
>
> Christiane Nüsslein-Volhard and Eric Wieschaus had opened a Pandora's box filled with a seemingly unmanageable jumble of genes, and transformed their hope for success into a reality. They showed that it really was possible to identify and classify genes that govern early embryogenesis in a rational way. The genes they found were surprisingly few: only 15. This success has paved the way for other developmental biologists to make pioneering discoveries.

2.6.2 Caesarean Sections and Neonatal Incubators

Scientists from the German-speaking world also pioneered techniques to aid childbirth and neonatal babies.

Although caesarean sections had been occasionally performed since ancient times, mothers usually did not survive the procedure. In 1881, Ferdinand Adolf Kehrer (German, 1837–1914, Fig. 2.203) first used a horizontal incision low on the abdomen that greatly reduced bleeding and maternal mortality.

In 1882, Max Sänger (German, 1853–1903, Fig. 2.203) demonstrated that the uterus could be sutured after a caesarean section to preserve the mother's ability to have future children.

Hermann Johannes Pfannenstiel (German, 1862–1909, Fig. 2.203) made further improvements to the surgical methods of caesarean sections in 1900. That final form of the technique, known as the Pfannenstiel incision, is still used today.

Caesarean sections were greatly aided by antiseptics (p. 165), anesthetics (p. 276), and later antibiotics (pp. 187–190), all of which were also developed by German-speaking creators.

In 1835, Johann Georg von Ruehl (Baltic German, 1769–1846, Fig. 2.204) invented and used the first neonatal incubators for premature babies. Such incubators became known as Ruehl's cradle and spread throughout Europe over the following decades.

Michael Cohn, later known as Martin Couney (German, 1870–1950, Fig. 2.204), moved to the United States and improved, mass-produced, and popularized incubators.

2.7 Aerospace Medicine, Prostheses, and Other Physiology

In addition to those areas already discussed in this chapter, scientists from the greater German-speaking world also made many important contributions to other topics in physiology, including:[28]

2.7.1. Aerospace medicine

2.7.2. Prostheses

2.7.3. Other aspects of anatomy, physiology, and zoology

2.7.1 Aerospace Medicine

As shown in Figs. 2.205–2.206, a number of German-speaking scientists made important early discoveries regarding high-altitude or aerospace medicine. Some major examples include:

- Arthur Berson (German, 1859–1942), a balloonist and meteorologist, conducted important research on the physiological effects of high altitudes. He used both high-altitude balloons and ground-based low-pressure chambers for that work, and he collaborated with Hermann von Schrötter, Reinhard Süring, and Nathan Zuntz.

- Arnold Durig (Austrian, 1872–1961) was a physician who conducted experiments on himself at high altitudes on mountains. He was a student of Nathan Zuntz.

- Adolf Löwy (German, 1862–1937), a physician, conducted experiments both on high mountains and in ground-based low-pressure chambers. He collaborated with Nathan Zuntz.

- Hermann von Schrötter (Austrian, 1870–1928) was a physician who designed a pressurized balloon cabin for very high altitudes. He studied physiological effects in balloons, on mountains, in ground-based pressure chambers, and in deep-sea divers. At various times he worked with Arthur Berson, Arnold Durig, Adolf Löwy, Reinhard Süring, and Nathan Zuntz.

- Reinhard Süring (German, 1866–1950) was a meteorologist who also studied the physiological effects of high altitudes using balloons and ground-based pressure chambers. He worked with Arthur Berson, Hermann von Schrötter, and Nathan Zuntz.

- Nathan Zuntz (German, 1847–1920), a physiologist, was the earliest of those listed here, and was essentially the founder of both high-altitude medicine and sports medicine. Over his long career, he trained and/or collaborated with Arthur Berson, Arnold Durig, Adolf Löwy, Hermann von Schrötter, and Reinhard Süring.

During World War II, Germany had a very large group of aerospace medicine researchers working on problems related to high-altitude aircraft, jets, rocket planes, ejection seats, and even piloted missiles and rockets. Those experts were rapidly scooped up by Allied countries at the end of the war, forming the basis for modern aerospace medicine in those countries. A large fraction of German aerospace medicine experts went to the United States, where they founded programs at the U.S. Air Force School of Aviation Medicine and the U.S. Naval Medical Research Institute (Figs. 2.207–2.208). Their expertise was invaluable for postwar military aviation, as well as for the later manned space program. Especially prominent members of this group of U.S.-based German aerospace medical experts included:

- Theodor Benzinger (German, 1905–1999) worked directly with the first U.S. astronauts to prepare them for spaceflight, yet is now nearly forgotten; if he is remembered at all by the modern world, it is for inventing the ear thermometer. Aerospace medicine expert Viktor Harsch summarized Benzinger's career path [Harsch 2007a]:

  > Theodore Benzinger was a pilot-physician who performed pioneering research—often involving self-experimentation—in areas related to flight at high altitude during World War II. Of greatest historical interest to those of us in aerospace medicine is his work on the effects of rapid decompression and related oxygen equipment. Benzinger was born in Stuttgart, Germany, on 28th August 1905. He studied medicine and natural sciences at the universities of Tuebingen, Munich, and Berlin. From 1934 to 1944, Benzinger headed the aeromedical laboratory "EMed" in Rechlin, where he was instrumental in conducting studies related to stratospheric flight, including self-experimentation with rapid decompression up to 19,000 m (62,320 ft). His Rechlin experiments made an important contribution to understanding the physiology and life-support requirements for high-altitude aviation and later work under space-equivalent conditions. Following World War II, Benzinger joined the staff of the U.S. Army Air Forces Aeromedical Center in Heidelberg. In 1947 he was recruited by "Operation Paperclip" to work at the U.S. Naval Medical Research Institute (NMRI) in Bethesda, MD, where he worked on various aspects of human physiology. He died as a U.S. citizen in Bethesda, MD, on 26th October 1999.

- Konrad Büttner (German, 1903–1970) specialized in environmental conditions from the lower atmosphere to the upper atmosphere to radiation in space. He worked closely with Theodor Benzinger, Hubertus Strughold, and other German-speaking scientists to apply that expertise to aerospace medicine.

- Fritz Haber (German, 1912–1998, not to be confused with the earlier chemist of the same name) was the brother of Heinz Haber. Both during and after World War II, he worked on aerospace projects and aerospace medicine. He and his brother proposed simulating zero-gravity conditions for short periods of time by sending astronaut trainees on parabolic flights in aircraft, and that became standard practice.

- Heinz Haber (German, 1913–1990) was the brother of Fritz Haber. He was a physicist and pilot, and worked on everything from nuclear power to aerospace projects, including parabolic flights for zero-gravity training.

- Hubertus Strughold (German, 1898–1986) was the leader of the German aerospace medicine experts both during and after the war. He tested himself in large centrifuges and pressure chambers in the 1930s and early 1940s, and headed the postwar programs to protect, equip, and train astronauts. In his biography, aerospace medicine experts Mark Campbell and Viktor Harsch wrote [Campbell and Harsch 2013, pp. 7, 10–11]:

  > Dr. Hubertus Strughold (1898–1986) is known as the “Father of Space Medicine”. The Space Medicine Branch of the Aerospace Medical Association initiated the “Hubertus Strughold Award” in 1963, given to the person each year for the greatest achievement in space medicine. [...]
  >
  > Dr. Hubertus Strughold became the first and only Professor of Space Medicine in 1958. Under his leadership, the school became a major center for basic and clinical investigations into the physiological and behavioral effects of spaceflight and the space environment. [...]
  >
  > Frequently misunderstood and a decade ahead of everyone else, but pressing forward with what he knew to be true and important; unwavering in his principles, beliefs, and ideas. As an example, Dr. Strughold never joined the Nazi party or allowed his staff to do so at a time when it would not only be advantageous to his career, but actually dangerous to not do so. He was as anti-Nazi as you could possibly be in his position without being arrested or executed. He specialized in aviation medicine at such an early time that he was discredited by his colleagues for his expansive ideas on future aeronautical possibilities. He then was a pioneer in the advancement of space medicine when the only activity was short unmanned suborbital flights using captured V-2s. He was pivotal in developing this discipline to such an extent that the U.S. was well prepared for the Mercury program in 1959. Finally, he was an advocate of the possibility of life on Mars and kept a “Mars jar” on his desk during the 1950s. This jar was growing lichen in an atmosphere of extremely dry, low pressure CO_2. [...]
  >
  > It is important that future debate of Dr. Strughold’s World War II activities be carried on with documented and well referenced facts[...]

2.7.2 Prostheses

Due to the combination of strong support for scientific innovation and the large numbers of people with war injuries, the German-speaking world led the development of prosthetic limbs from the beginning of the nineteenth century onward.

While simple, rigid artificial limbs had been used since antiquity, in 1808, Albrecht Ludwig Berblinger (German states, 1770–1829) developed the first prosthetic legs with movable joints, which made the legs much more practical to use (Fig. 2.209). Berblinger also made early attempts at developing manned gliders [Harsch and Kriebel 2006].

In the 1890s, Jakob Riedinger (German, 1861–1917, Fig. 2.210) developed a corresponding prosthetic arm with movable joints, the "Würzburg working arm." In addition, from the 1890s through World War I, he established and helped to run national programs to treat and assist the disabled.

During World War I, Ferdinand Sauerbruch (German, 1875–1951) invented the first prosthetic arms that could be controlled by residual arm stump muscles, a particularly useful design that became known as the "Sauerbruch arm" (Fig. 2.210). In 1904, Sauerbruch also invented a pressurized chamber (the "Sauerbruch chamber") for much more safely opening the thorax of a patient to conduct operations on the heart or lungs.

Georg Schlesinger (German, 1874–1949, Fig. 2.210) worked with both Jakob Riedinger and Ferdinand Sauerbruch to design and build improved prosthetic arms and legs during and after World War I. Schlesinger also spent much of his career improving the standardization, testing, and calibration of machine tools.

During and after World War II, Ulrich Henschke (German, 1914–1980) and Hans Mauch (German, 1906–1984) developed the Swing-aNd-Stance (S-N-S) hydraulically controlled prosthetic leg, which has been used worldwide for many decades since then (Fig. 2.211). They also worked on prosthetic arms, vision systems for the blind, methods of interfacing electronics to the human nervous system, aerospace medicine, and aviation controls and simulators. In addition, Henschke developed brachytherapy methods for treating cancer. Mauch also played a key role in the early development of jet engines and jet aircraft (p. 1764). For much more information on Henschke and Mauch, see Section A.2.

2.7.3 Miscellaneous Anatomy, Physiology, and Zoology

Scientists from the greater German-speaking world also made many important contributions regarding other aspects of anatomy, physiology, and zoology. A few illustrative examples are shown in Figs. 2.212–2.214 and discussed below:

Theodor Billroth (German/Austrian, 1829–1894) established and taught many of the key principles of modern gastrointestinal surgery (Fig. 2.212).

Ernst von Brücke (German, 1819–1892) conducted research on the anatomy and physiology of everything from chameleons' color changes to human language.

Karl Friedrich Burdach (German states, 1776–1847) studied the anatomy and physiology of the brain and other organs, and popularized the term "biology" for the study of organisms.

Julius Cohnheim (German, 1839–1884) made important discoveries in immunology, inflammation, neuromuscular junctions, histology, and other areas.

Johann Friedrich Dieffenbach (German states, 1792–1847) greatly advanced reconstructive and plastic surgery.

Gustav Gärtner (Austrian, 1855–1937) did important work in renal physiology, blood pressure measurement, nutrition, and other areas.

Leopold Gmelin (German states, 1788–1853) conducted research on digestive physiology, biochemistry, cellular pigments, and other topics.

Willi Hennig (German, 1913–1976) performed extensive work in comparative zoology and founded the field of phylogenetic systematics or cladistics.

Rudolf Albert von Kölliker (Swiss, 1817–1905) made discoveries in comparative zoology, embryology, histology, and the anatomy and physiology of many human organs.

Adolf Kussmaul (German, 1822–1902) was a pioneering physician who gave the first descriptions of mesenteric embolism, polyarteritis nodosa, progressive bulbar paralysis, the labored breathing of diabetic ketoacidosis, and the early emotional effects of mercury poisoning. He also worked to develop novel techniques such as esophagoscopy, gastric lavage, gastroscopy, and pleural tapping. He discovered dyslexia (p. 261) and the anti-inflammatory effects of acetanilide (p. 269) too.

Carl Ludwig (German, 1816–1895) wrote a textbook on human physiology (1852–1856) and worked in many areas of physiology, including blood pressure, renal physiology, and anesthesia.

Johannes Peter Müller (German states, 1801–1858) made several important discoveries in physiology and other fields of biology, and published his *Handbuch der Physiologie des Menschen* (*Handbook of Human Physiology*) during the period 1833–1840.

Friedrich Tiedemann (German states, 1781–1861) made contributions to neuroanatomy, osteology, cancer, evolution, and other topics.

Theodor Billroth (in yellow, 1829–1894) pioneered abdominal surgery

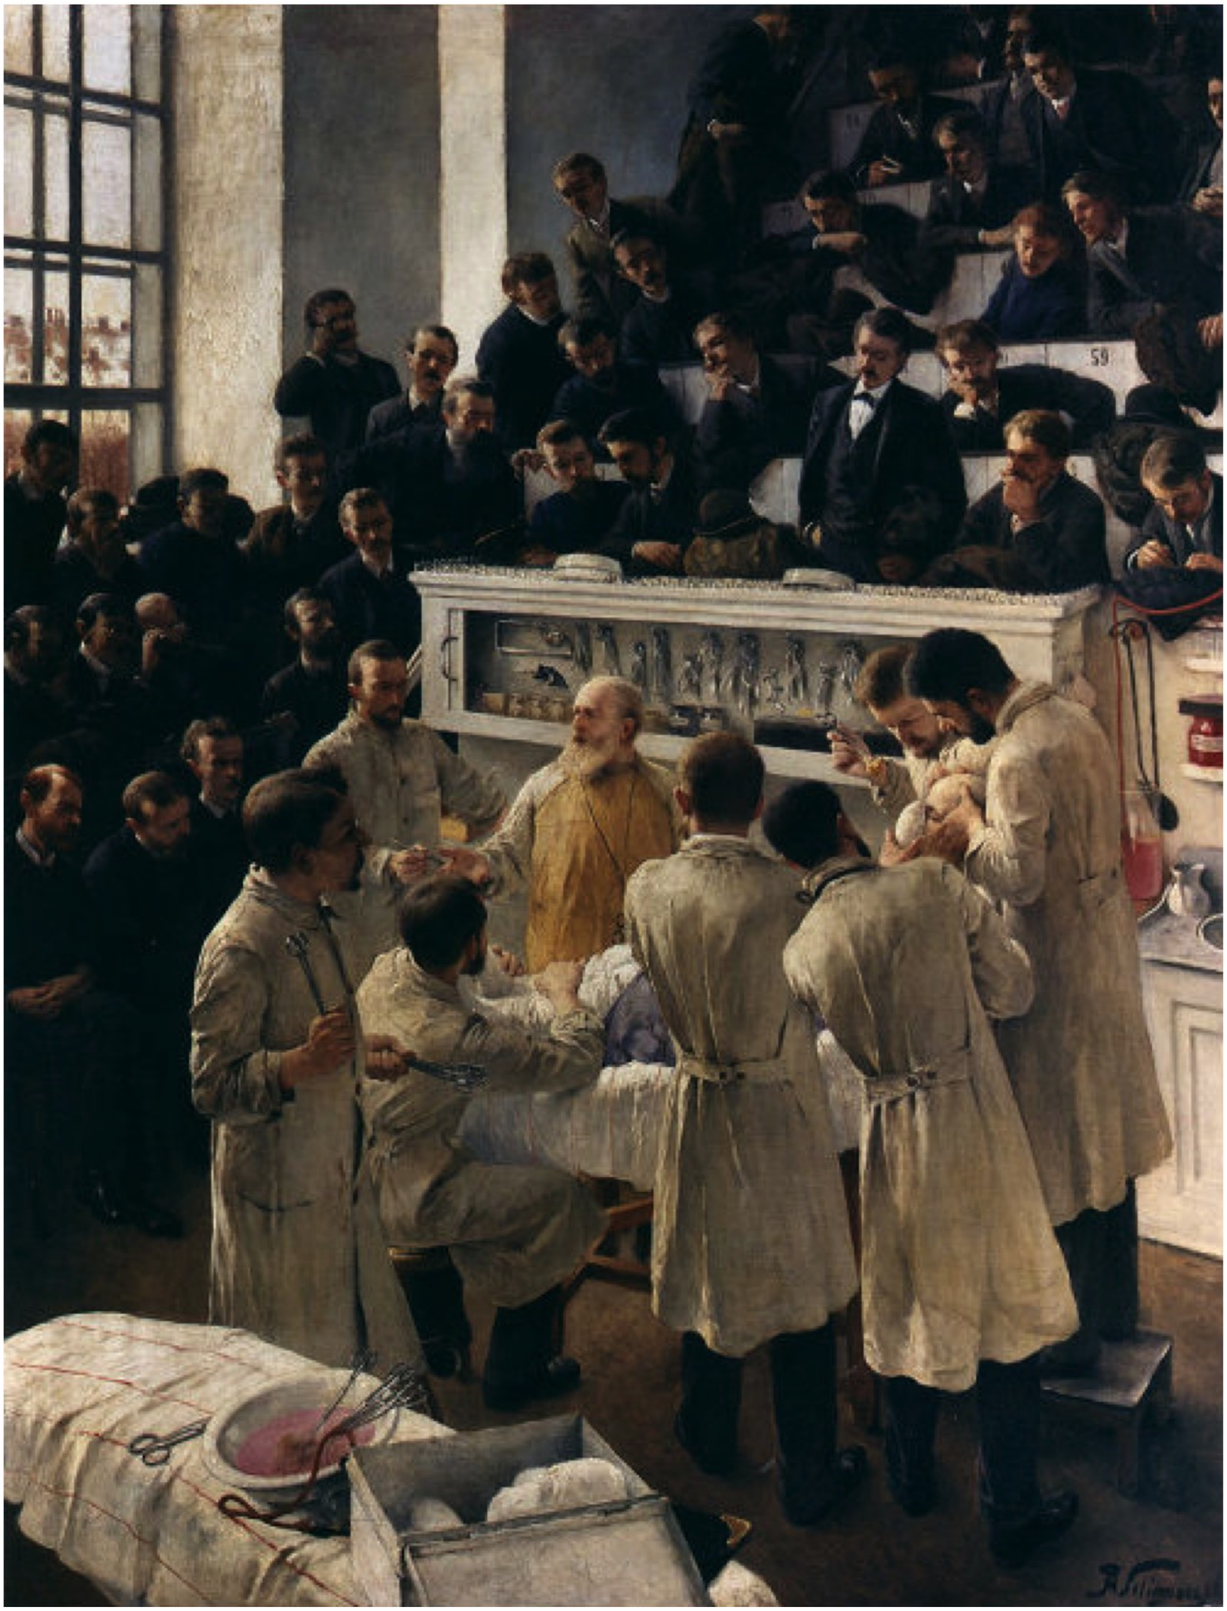

Figure 2.212: Theodor Billroth pioneered abdominal surgery.

2.8 Botany

Scientists from the greater German-speaking world made many important discoveries in botany, including:[29]

2.8.1. How chlorophyll facilitates the process of photosynthesis.

2.8.2. Other aspects of plant physiology and genetics.

2.8.1 Photosynthesis

As shown in Fig. 2.215, plant cells are similar to animal cells, but they are surrounded by a cell wall and also possess chloroplasts. The chloroplasts contain chlorophyll, a specialized porphyrin molecule that absorbs light energy, which is then converted into stored chemical energy in a process called photosynthesis. The structure of chlorophyll and the biochemical steps involved in photosynthesis are quite complex, and a number of scientists were involved in elucidating their details (Figs. 2.216–2.218). Due to the overlapping and scientifically complex nature of their work, these creators are simply listed alphabetically below with very brief descriptions of their contributions.

Hans Fischer (German, 1881–1945) won the Nobel Prize in Chemistry in 1930 for his discoveries regarding the structure and synthesis of chlorophyll (as well as heme from hemoglobin–see p. 324). In awarding Fischer the Nobel Prize, Professor H.G. Söderbaum, Chairman of the Nobel Committee for Chemistry of the Royal Swedish Academy of Sciences, praised his work [https://www.nobelprize.org/prizes/chemistry/1930/ceremony-speech/]:

> [...] Even if I add that Fischer has demonstrated the occurrence of haemin in yeast, all this is overshadowed by the fact that, chemically speaking, the pigment of green plants, i.e. chlorophyll, is closely related with the red blood pigment, and even derives, as Fischer has shown, from exactly the same parent substance, as regards the porphyrins.
>
> This shows that Nature in spite of her extravagant diversity was sufficiently economical to use exactly the same building material when constructing these two substances which are so greatly different in appearance and occurrence.
>
> Having completed his work on the blood pigments and their components by the haemin synthesis, Fischer turned with undiminished energy to research into chlorophyll. In this field, where a scientist has previously gained a Nobel Prize, but where much work remained to be done, conditions are even more complicated and the difficulties as a consequence are even greater than in the other field. Nevertheless, Fischer obtained results which are so important that the Academy has considered it fitting to include them in the award.

---

[29] Bateson 1909; Corcos and Monaghan 1993; Deichmann 1996; Dostal 2016; Edelson 1999; Goppelsröder 1901; Henig 2000; Jahn 2004; Junker 2004; Kaplan and Cooke 1996; Magner 2002; Mawer 2006; Miller 1988; Richards 2004; Taschwer 2016; Wulf 2015.

James Franck (German, 1882–1964) was a quantum and nuclear physicist who spent his whole career studying various ways that light can interact with matter; he won the Nobel Prize in Physics in 1925 for part of that work, as discussed on p. 893. As just one aspect of that general interest, Franck conducted important experimental and theoretical analyses of the physics underlying photosynthetic interactions between light and chlorophyll molecules.

Friedrich Goppelsröder (Swiss, 1837–1919) demonstrated one-dimensional chromatography methods both in filter paper and in capillary tubes in 1861, and continued working to improve and to apply chromatography for several decades [Schönbein 1861; Goppelsröder 1861]. In particular, he used chromatography to separate and analyze the colored pigments from a wide variety of plant leaves [Goppelsröder 1901]. Some of the later scientists listed in this section ultimately found that some of those separated pigments were various forms of chlorophyll and related photosynthetic pigments. See pp. 711–714.

Like Hans Fischer but much earlier, Felix Hoppe-Seyler (German, 1825–1895) also purified and analyzed both hemoglobin and chlorophyll, and his studies became the foundation for the later work by Fischer and others.

Robert Huber (German, 1937–), Johann Deisenhofer (German, 1943–), and Hartmut Michel (German, 1948–) identified the mechanisms of photosynthesis in certain types of bacteria that can convert sunlight. Photosynthetic bacteria are environmentally important in their own right, and they were also the ancestors of photosynthetic plant chloroplasts. For this research, Huber, Deisenhofer, and Michel won the Nobel Prize in Chemistry in 1988. Professor Bo G. Malmström of the Royal Swedish Academy of Sciences explained the importance of their discoveries [https://www.nobelprize.org/prizes/chemistry/1988/ceremony-speech/]:

> For a long time it has been impossible to prepare membrane-bound proteins in a form allowing the determination of the detailed structure in three dimensions. [...] But the situation had actually drastically changed in 1982, when Hartmut Michel thanks to systematic experiments succeeded in preparing highly ordered crystals of a photosynthetic reaction center from a bacterium. With these crystals he could in the period 1982–1985, in collaboration with Johann Deisenhofer and Robert Huber, determine the structure of the reaction center in atomic detail.
>
> The structural determination awarded has led to a giant leap in our understanding of fundamental reactions in photosynthesis, the most important chemical reaction in the biosphere of our earth. But it has also consequences far outside the field of photosynthesis research. Not only photosynthesis and respiration are associated with membrane-bound proteins but also many other central biological functions, e. g. the transport of nutrients into cells, hormone action or nerve impulses. Proteins participating in these processes must span biological membranes, and the structure of the reaction center has delineated the structural principles for such proteins. Michel's methodological contribution has, in addition, the consequence that there is now hope that we can determine detailed structures also for many other membrane proteins. Not least important is the fact that the reaction center structure has given theoretical chemists an indispensable tool in their efforts to understand how biologic electron transfer over very large distances on a molecular scale can occur as rapidly as in one billionth (American English, trillionth) of a second. In a longer perspective it is possible that such research can lead to important energy technology in the form of artificial photosynthesis.

Jan Ingenhousz (Dutch, worked in Austria, lived 1730–1799) demonstrated that plant leaves produce oxygen when in the light and carbon dioxide when in the dark, and that part of a plant's mass must come from the air.

Hans Kornberg (German, 1928–) studied photosynthetic pathways in bacteria and related those to photosynthetic molecules and reactions in plants.

Max Rudolf Lemberg (German, 1896–1975) spent his career investigating the structure and function of porphyrins, including those for chlorophyll, hemoglobin, and several cytochromes.

Hilde Levi (German, 1909–2003), a quantum and nuclear physicist, worked with James Franck to purify chlorophyll molecules and analyze the light absorption and emission spectra of chlorophyll.

Julius von Mayer (German, 1814–1878) clearly articulated and was an important early advocate of the general principle of photosynthesis, that plants convert absorbed light energy into stored chemical energy.

Helmut Metzner (German, 1925–1999) made highly accurate measurements of photosynthetic reactions that refined our understanding of the detailed processes involved.

Julius von Sachs (German, 1832–1897) demonstrated that photosynthesis in leaves produces starch molecules, a key discovery in understanding the fundamental role of photosynthesis.

Nicolas-Théodore de Saussure (Swiss, 1767–1845) made careful experimental measurements demonstrating that photosynthetic reactions require both water and carbon dioxide as input materials.

Cornelius Bernardus van Niel (Dutch, 1897–1985) pioneered the study of photosynthetic pathways in bacteria. His work was later continued by Hans Kornberg, Robert Huber, Johann Deisenhofer, and Hartmut Michel.

Otto Heinrich Warburg (German, 1883–1970) investigated the catalytic mechanism and quantum efficiency involved in photosynthesis. He should not be confused with his distant older cousin Otto Warburg (1859–1938), who made other contributions to botany (p. 414). Otto Heinrich Warburg won the Nobel Prize in Physiology or Medicine in 1931 for his work on cellular respiration, which is essentially photosynthesis with all of its biochemical steps run in reverse (p. 147).

Building upon the earlier work by Friedrich Goppelsröder, Richard Willstätter (German, 1872–1942) identified different types of chlorophyll and other plant pigment molecules and determined their empirical formulas. For those discoveries, he won the Nobel Prize in Chemistry in 1915. At the award ceremony, Professor O. Hammarsten, Chairman of the Nobel Committee for Chemistry of the Royal Swedish Academy of Sciences, described the importance of Willstätter's work [https://www.nobelprize.org/prizes/chemistry/1915/press-release/]:

> The difficulties, however, which confront research scientists in this field have been so great that until very recently they have prevented a successful study of the problem of chlorophyll. Willstätter is the first, jointly with several of his students, to have been successful in overcoming these difficulties by working out new and very valuable methods and by extensive investigations carried out with masterly experimental skill. By the new and important discoveries resulting from these investigations he has been able to elucidate in all its essential parts the question of the chemical nature of chlorophyll. [...]

The most important part of Willstätter's investigations is, nevertheless, that relating to the detection of the chemical structure of chlorophyll. He has shown that chlorophyll is an ester, which on saponification with alkali can be split up into a previously unknown alcohol called "phytol", which represents about one third of the molecule, and a colour component called "chlorophyllin", containing magnesium, which forms the remaining part. He has more closely investigated these two components both individually and for their transformation and decomposition products. Furthermore, he has found that this splitting-up of chlorophyll into the two mentioned main components can also take place as a result of the action of an enzyme occurring in the leaves, which he has called "chlorophyllase", and hence he has been able to elucidate the nature of the crystallized chlorophyll. [...]

A very important section of Willstätter's work on the chemical structure of chlorophyll is represented by his investigations into the colour components, the "chlorophyllin", and other "phyllins" and derivatives formed from it. These investigations are of particular interest with regard to the question of the relationship between blood pigment and chlorophyll. [...]

He has also prepared in a pure state and studied exhaustively the yellow pigments, the so-called carotenoids, which occur together with chlorophyll in the leaves of plants. By means of the results obtained regarding both these yellow pigments and the chlorophylls he has paved the way for new biological researches into the part played by the different leaf pigments in the assimilation of carbonic acid.

2.8.2 Other Aspects of Botany

There were a huge number of scientists in the predominantly German-speaking scientific world who made important discoveries regarding plant properties other than photosynthesis. This section can only briefly mention a few illustrative examples (Figs. 2.219–2.222).

Willem Hendrik Arisz (Dutch, 1888–1975) contributed to many areas of botany over his long career, but is perhaps best remembered for his work on the mechanisms of phototropism.

Franz Andreas Bauer (Austrian, 1758–1840) discovered plant cell structures under the microscope and produced thousands of highly detailed color paintings and drawings of the microscopic and macroscopic features of a vast variety of plants.

Martinus Beijerinck (Dutch, 1851–1931) discovered nitrogen fixation, the process by which bacteria living in root nodules of plants convert atmospheric nitrogen gas into ammonia that plants can absorb and utilize.

Alexander Braun (German, 1805–1877) made important discoveries regarding plant morphology, phyllotaxis, plant cell structure, and other aspects of botany.

Ferdinand Cohn (German, 1828–1898) investigated algae and plants under the microscope, recognized that algae are simple single-celled plants, and conducted experiments on plant physiology.

Friedrich Johann Franz Czapek (Austrian/Czech, 1868–1921) studied and synthesized new biochemical discoveries that were applicable to plants in his highly influential three-volume reference work, *Biochemie der Pflanzen*.

Heinrich Anton de Bary (Germany, 1831–1888) identified and studied plant pathogens such as the fungi that cause potato (late) blight and stem (wheat) rust, showed that lichens are a symbiosis of algae and fungi, and studied other aspects of algae and plant physiology.

Augustin de Candolle (Swiss, 1778–1841) developed and published a hugely detailed system of classifying plants and proposing their potential evolutionary relationships. He also demonstrated intrinsic circadian rhythms in plants kept under conditions of constant light.

Gottlieb Haberlandt (Austrian, 1854–1945) developed plant cell tissue culture and also discovered totipotency, the ability of some "stem" cells to give rise to any type of specialized cell in an organism, in 1902. He was the father of Ludwig Haberlandt, who developed oral contraceptives (p. 354).

Wilhelm Hofmeister (German, 1824–1877) discovered the alternation of generations in plants, was one of the first scientists to observe and record plant chromosomes under the microscope, greatly advanced the study of plant embryology, and proposed a theory for the evolution of plant species. His botanical discoveries were so numerous and so revolutionary that he deserves far more fame than he has generally received [Kaplan and Cooke 1996].

Alexander von Humboldt (Prussian, 1769–1859), traveled the world conducting scientific studies, and essentially founded the field of botanical geography. He also made other contributions to botany, as well as geography, meteorology, archaeology, and other subjects [Wulf 2015].

Gregor Mendel (Austrian, 1822–1884) discovered the rules of genetics using plants he grew at his monastery (p. 96). He also studied asexual reproduction in hawkweed and identified several new species of plants.[30]

Franz Meyen (Prussian, 1804–1840, Fig. 2.1), a botanist and microscopist, published a very important series of plant physiology books in the 1830s. Among other critical insights during his short life, he wrote that plants were divided into many similar cells, and that new cells arose from the division of existing cells.

Hugo von Mohl (German, 1805–1872) observed the structure of plant cells under the microscope and recorded cell division in algae in 1835. He also spent decades observing and cataloging the microscopic and macroscopic structures of a wide range of plants.

Ernst Münch (German, 1876–1946) made major discoveries in plant physiology, tree breeds and species, pine resin, and plant pathology (including blue stain fungi and disease resistance). He is best remembered for his pressure flow hypothesis of nutrient transport in plants.

Wilhelm Pfeffer (German, 1845–1920) was responsible for important findings regarding growth, movement, and metabolism in plants. He also discovered the significance of osmotic pressure, and he developed methods to measure it.

Wilhelm Ruhland (German, 1878–1960) had a long career conducting botanical research, but his greatest contribution was writing the 18-volume *Handbuches der Pflanzenphysiologie*, which was finally published at the end of his life.

Matthias Schleiden (German 1804–1881, Fig. 2.2) studied a variety of plants and plant tissues under the microscope and was one of the first scientists to recognize that larger organisms are divided into many similar cells. He studied the cell nucleus, cell division, and other aspects of plant cells.

Eduard Strasburger (Polish, studied and worked in Germany, 1844–1912) studied the embryology of gymnosperms and angiosperms, monitored plant chromosomes in cell division, and made other contributions to plant physiology and cell biology.

Gottfried Reinhold Treviranus (Bremen, 1776–1837) proposed a theory of plant evolution and studied the relationships among plant species. He was the older brother of Ludolph Treviranus.

Ludolph Christian Treviranus (Bremen, 1779–1864) made a wide variety of contributions to plant taxonomy, embryology, and physiology. He was the younger brother of Gottfried Treviranus.

Otto Warburg (German, 1859–1938) was an important expert on tropical agriculture. He should not be confused with his distant younger cousin Otto Heinrich Warburg (1883–1970, p. 407).

Frits Warmolt Went (Dutch, 1903–1990) studied plant hormones. In 1927, he discovered the role of the plant hormone auxin in phototropism.

Fritz von Wettstein (Austrian, 1895–1945) made a number of important discoveries regarding chloroplast genetics and plant chromosomes. He was the son of Richard Wettstein von Westersheim.

Richard Wettstein von Westersheim (Austrian, 1863–1931) developed and published an extremely detailed system of classifying plants, and was the father of Fritz von Wettstein.

Chapter 3

Creators and Creations in Chemistry and Materials Science

Alle Arnzneien sind auf der Erde, aber es fehlen die Menschen, die sie pflücken würden. Sie sind zur Ernte gereift, aber die Schnitter sind nicht gekommen. Wenn einmal die Schnitter der rechten Arznei da sein werden, dann werden wir ohne Hinderung durch leere Sophistik die Aussätzigen reinigen und die Blinden sehend machen. Denn diese Kraft liegt in der Erde und sie wächst überall. [...]

All the remedies are on earth, but we lack the people to gather them. They are ready to be harvested, but the reapers have not come. But one day the reapers of the right remedies shall come, and undeterred by empty sophistry we will cleanse the lepers and make the blind see. For this power is concealed in the earth, and it grows everywhere. [...]

Die Natur ist so sorgfältig und genau in ihren Dingen, daß man sie ohne große Kunst nicht verwenden kann; denn sie bringt nichts an den Tag, was an sich vollendet wäre. Alles hat der Mensch zu vollenden. Diese Vollendung heißt: Alchemie... Und der ist ein Alchemist, der alles, was in der Natur den Menschen zum Nutzen wächst, zu seinem von ihr bestimmten Ende führt. [...] Deswegen soll mehr Fleiß darauf verwendet werden, um mehr daraus zu gestalten! [...]

Nature is so careful and exact in her creations that they cannot be used without great skill; for she does not produce anything that is perfect in itself. Man must bring everything to perfection. This work of bringing things to their perfection is called alchemy... And he is an alchemist who carries what nature grows for the use of man to its destined end. [...] For this reason more diligence should be spent on alchemy, in order to obtain still greater results! [...]

Gott hat Eisen geschaffen, aber nicht das, was daraus gemacht werden soll... Das Weitere hat Er dem Feuer anbefohlen und dem Vulcanus, der des Feuers Herr ist... Daraus folgt, daß das Eisen zuerst von seinen Schlacken gereinigt und dann zu dem geschmiedet werden muß, was aus ihm entsehen soll. Das nennt sich Alchemie, das ist der Schmelzer—der Schmied—, der Vulcanus heißt. Was das Feuer tut, ist Alchemie—auch im Ofen, oder auch im Küchenherd.	God created iron but not that which is to be made of it... He enjoined fire, and Vulcan, who is the lord of fire, to do the rest... From this it follows that iron must be cleansed of its dross before it can be forged. This process is alchemy; its founder is the smith Vulcan. What is accomplished by fire is alchemy—whether in the furnace or in the kitchen stove.

Paracelsus. ca. 1536. In Jolande Jacobi, ed. 2002. *Paracelsus: Lebendiges Erbe.* St. Goar: Reichl. pp. 96–97. English translation adapted from Norbert Guterman.

As with biology, during the nineteenth century, intellectual leadership in chemistry and materials science passed from scientists in other countries (primarily France, the United Kingdom, and Sweden) to German-speaking scientists.[1]

For coverage of major portions of the history of chemistry and materials science in the German-speaking world, see: Abelshauser et al. 2004; Brock 1993; Bugge 1955; Coffey 2008; Deichmann 2001; Drummer and Zwilling 2007; Engels et al. 1989; Farber 1961; Haber 1958, 1971; Ihde 1984; Johnson 1990; Kahlert 2002; Karlsch2016; Lesch 2000; Maier 2015; Marsch 1994a; Neufeldt 2003; Partington 1935, 1957, 1964; Peppas 2013; Rosner 2004; Sasuly 1947; Scerri 2006; Schwenk 2000; Soukup 2007; Teltschik 1992; Ungewitter 1938; Weeks and Leicester 1968; Welsch 1981; Werner 2017.

I have deliberately left a blank space where images of some creators or creations should go. Those are people or projects that I felt were important enough that they should definitely be shown in this book, yet I have not yet been able to locate a suitable image that I have permission to use, despite my searches in Europe and in the United States. If readers have any relevant images and could send them to me, I would be very grateful and will include them in future editions of this book. Even where a suitable photo cannot be located, I believe that leaving a blank space pays tribute both to the scientific importance of that creator or creation and to how that historical fact has been very nearly forgotten.

As covered in this chapter, creators from the predominantly German-speaking central European research world then made enormous contributions to:

3.1. Inorganic chemistry

3.2. Organic chemistry

3.3. The chemistry of foods and drinks

3.4. Chemical explosives

3.5. Chemical warfare agents and pesticides

3.6. Physical chemistry

3.7. Film photography

3.8. Materials science

3.9. Other aspects of chemistry

German-speaking creators also made numerous contributions to other chemistry-related areas such as biochemistry (Chapter 2), earth science (Chapter 4), quantum and statistical physics (Chapter 5), and nuclear chemistry (Chapter 8).

In 1946, the American journalist Charles Lester Walker provided a useful contemporary perspective on chemistry- and materials-related creations that were transferred out of the German-speaking world [Charles Walker 1946]:

> Mica was another thing. None is mined in Germany, so during the war our Signal Corps was mystified. Where was Germany getting it?
>
> One day certain piece of mica was handed to one of our experts in the U.S. Bureau of Mines for analysis and opinion. “Natural mica,” he reported, “and no impurities.”
>
> But the mica was synthetic. The Kaiser Wilhelm Institute for Silicate Research had discovered how to make it and—something which had always eluded scientists—in large sheets.
>
> We know now, thanks to FIAT teams, that ingredients of natural mica were melted in crucibles of carbon capable of taking 2,350 degrees of heat, and then—this was the real secret—cooled in a special way. Complete absence of vibration was the first essential. Then two forces directly perpendicular to each other were applied. One, vertically, was a controlled gradient of temperature in the cooling. At right angles to this, horizontally, was introduced a magnetic field. This forced the formation of the crystals in large laminated sheets on that plane.

> "You see this . . ." the head of Communications Unit, TIIB, said to me. It was metal, and looked like a complicated doll's house with the roof off. "It is the chassis or frame, for a radio. To make the same thing, Americans would machine cut, hollow, shape, fit—a dozen different processes. This is done on a press in one operation. It is called the 'cold extrusion' process. We do it with some soft, splattery metals. But by this process the Germans do it with cold steel!
>
> Thousands of parts now made as castings or drop forgings or from malleable iron can now be made this way. The production speed increase is a little matter of one thousand per cent."
>
> This one war secret alone, many American steel men believe, will revolutionize dozens of our metal fabrication industries.
>
> In textiles the war secrets collection has produced so many revelations, that American textile men are a little dizzy. There is a German rayon-weaving machine, discovered a year ago by the American 'Knitting Machine' Team, which increases production in relation to floor space by one hundred and fifty percent. Their "Links-Links" loom produces a ladderless, runproof hosiery. New German needle-making machinery, it is thought, will revolutionize that business in both the United Kingdom and the United States. There is a German method for pulling the wool from sheepskins without injury to hide or fiber, by use of an enzyme. Formerly the "puller"—a trade secret—was made from animal pancreas from American packing horses. During the war the Nazis made it from a mold called aspergil paraciticus, which they seeded in bran. It results not only in better wool, but in ten per cent greater yield.
>
> Another discovery was a way to put a crimp in viscose rayon fibers which gives them the appearance, warmth, wear resistance, and reaction-to-dyes of wool. The secret here, our investigators found, was the addition to the cellulose of twenty-five per cent fish protein.
>
> But of all the industrial secrets, perhaps, the biggest windfall came from the laboratories and plants of the great German cartel, I. G. Farbenindustrie. Never before, it is claimed, was there such a store-house of secret information. It covers liquid and solid fuels, metallurgy, synthetic rubber, textiles, chemicals, plastics. drugs, dyes. One American dye authority declares:
>
> *It includes the production know-how and the secret formulas for over fifty thousand dyes. Many of them are faster and better than ours. Many are colors we were never able to make. The American dye industry will be advanced at least ten years.*

A 29 July 1945 press release from the U.S. Foreign Economic Administration confirmed Walker's assessment of how advanced German science and engineering were, and also cited many additional examples, mainly in chemistry and materials science [NARA RG 40, Entry UD-75, Box 12, Folder Publicity, Advance Release FEA-575]:

Among the new developments uncovered so far are the following:

A plane with a ceiling several thousand feet higher than any American plane.

Process for welding side seams on tin cans by machine instead of by hand, as in this country.

New applications of radiation devices in fields not heretofore explored in the U.S.

New and improved X-ray tubes for cancer therapy and industrial purposes.

Flexible high tension cables that withstand double the voltage of American made cables of the same size.

Tungsten substitutes for use in the manufacture of armor-piercing shells and cutting tools for machining metals.

Power circuit breakers with construction details unfamiliar in the U.S.

New uses of waste cellulose materials for the manufacture of fats for animal feed.

Improved techniques in the fermentation of yeast from wood sugar in the production of both human and cattle food.

Improved techniques for the production of synthetic petroleum products.

Hydrogenation plants operating at extremely high pressures.

New catalysts permitting the Germans to convert oil to high octane gasoline more quickly than was known here.

Details on German refinements in the gas synthesis method of producing liquid fuels and lubricants from coal.

New processing methods in the field of synthetic rubber.

New data on continuous polymerization processes in plastics manufacture.

New data on acetylene and electro-chemical processes.

Information on high temperature alloys unknown in the U.S.

Production of high grade nitro-cellulose from lower grade wood pulp with stability superior to the same product made from high grade pulp in the U.S.

Gottfried Plumpe, a historian of science who wrote one of the most comprehensive studies of I.G. Farben's chemical research programs [Plumpe 1990], summarized his findings about why the German chemical industry was so innovative [Caron 1995, pp. 163–173]:

> When the companies merged to form the IG Farben in 1926 they had a total of 25 large laboratories employing over 3,700 people. [...]
>
> Cooperation with external researchers and research institutes traditionally played an important role in developing the innovative potential of the company. It is no exaggeration to say that there was a close network of cooperation between chemical companies and universities, and that this formed the basis for the development of the German chemical industry. Outstanding examples from the years prior to the merger include the synthesis of indigo and ammonia, the development of the first medicines and chemotherapy. Famous names from this period include Adolf von Baeyer, Fritz Haber, Wilhelm Filehne, Paul Ehrlich and Hermann Staudinger.
>
> The basic research carried out by external institutes was essential for industrial R&D. The universities also ensured a supply of qualified personnel both for the research laboratories and for the production plants. A close and trusting relationship between the company and universities was thus an integral part of IG Farben's research strategy. The importance accorded to this is reflected by the fact that the Board of Management itself rook charge of maintaining these contacts. The founding fathers of IG, men like Carl Duisberg, Carl Bosch and Arthur von Weinberg, regarded themselves at least partially as scientists and undertook this task personally. In 1931, when the Central Committee was set up, it was agreed unanimously that one of its nine members should have special responsibility for these research contacts.
>
> IG Farben has often been accused of having no uniform R&D strategy, unlike the Anglo-American corporations. I do not believe that this is true. IG management most definitely did have a basic objective—we need only think of its declared aim of becoming a diversified company capable of synthesizing all organic products. Given the size of the company and above all the diversity of its activities this objective could never manifest itself in the form of a single "grand design". The most important factor behind the company's R&D policy was the fact that all members of the management team shared the basic conviction that R&D was essential for the company's future and that there was general agreement on the basic aims.
>
> In the relatively prosperous years following the merger, when the company was earning high profits, this meant that almost every project received authorization and financial support. Costs expanded accordingly, with research expenses reaching ten per cent of sales in the 1920s, the highest level in the company's short history.
>
> [...] About a third of all university graduates working for IG were employed in research. In 1929/30 there were about 1,100 scientists on the payroll. By 1932 the number had fallen by about 100, partly through redundancies and partly through natural wastage. During the 1930s the number of researchers gradually rose again, reaching a high point of 1,300 in 1940. During the war it fell back to 1,000. This decline becomes more significant if we compare it with the development of the total workforce. In 1929 research scientists

> represented just one per cent of the workforce. This rose to 1.5 per cent during the Depression because considerably more labourers and clerical staff lost their jobs than researchers. By 1939 researchers only represented 0.8 per cent of the workforce and by 1944 this had dropped to 0.5 per cent. [...]
>
> It is never as easy to quantify the results of R&D and their economic impact as it is to describe organizational structures. It is a well-known fact that the number of patents is only a very rough indicator because it says nothing about the importance of the processes and products they refer to. Nevertheless, the figures give some indication of activity. IG Farben obtained an extremely large number of patents, roughly corresponding to its spending on R&D.
>
> The number of patent applications rose in the 1920s, dropped during the Depression and then increased again through the 1930s. Between 1928 and 1930 IG Farben submitted more than 2,000 patent applications a year in Germany and almost 10,000 worldwide. In the thirties IG Farben had more patents than any other company in the world. At the start of 1939 it held over 5,000 patents in Germany and about 34,000 in other major countries throughout the world, including 5,300 in the USA, about 4,000 in the UK, 3,700 in France, 2,300 in Italy and nearly 900 in Japan. The majority—a good third of the German patents—concerned dyestuffs, while 13 per cent were for organic intermediates and solvents, about 10 per cent each were for inorganic products and medicines, eight per cent for photographic products and fibres and about six per cent for the hydrogenation of mineral oil.

Plumpe also gave an overview of the wide range of innovations that came from the German chemical industry [Caron 1995, pp. 163–173]:

> A few details of the innovations made by IG Farben should give a clearer idea of what all this meant. In the 1920s by far the largest project was the synthesis of mineral oil, which was brought to a successful conclusion in 1932. The basic principle comprised catalytic hydrogenation of solid carbon from lignite or hard coal, yielding aviation and motor fuel, lubricants and hydrogenation gas. The high energy requirement meant that these processes were less economical than those based on petrochemical feedstocks, and they were only used in Germany during the Nazi period. However, the R&D work in this field provided a wealth of material that was of wider use to the petrochemical industry and is still important today.
>
> The second most important project was the synthesis of rubber, a project which the companies had worked on prior to the merger and which was taken up again in 1926. The project was largely abandoned during the Depression, but in 1935 came the breakthrough with the development of styrene butadiene rubber. A modified form of this synthetic rubber is the most important commodity rubber produced today. IG Farben was also a pioneer in the development of plastics. Its achievements include polystyrene (1929), the development of polyvinylchloride (PVC) into a usable engineering plastic (1931) and the discovery of polyurethane in 1937. IG also developed a polyamide-based synthetic fibre (Perlon) at around the same time as Du Pont (1935) and in 1941 it produced the first polyacrylonitrile fibre.

Until the discovery of penicillin, IG was also a world leader in the field of chemotherapy. Milestones in this field include the development of antimalarial drugs based on quinolone derivatives, for example, Plasmochin (1924), Atebrin (1930) and, above all, the first antibacterial sulphonamide (1935). A pioneering innovation in the field of crop protection, phosphoric acid ester (mid-1930s), also belongs to the IG era.

The development of organic intermediates was extremely important for many areas of the chemical industry from dyestuffs through pharmaceuticals and crop protection agents to films and plastics. The products developed are too numerous to be listed here, but it is no exaggeration to say that the success of IG was largely due to its dominant position in this field and that the organic intermediates were the foundation stone for the development of modern chemical technology. In order to give a complete picture of the breadth of research in the IG Farben, its work on inorganic and metal chemistry and its pioneering role in the development of colour photography should also be mentioned.

Since there are no precise data on the contribution made by new products to the company's sales and earnings, it is not easy to quantify their importance, and above all their economic impact. However, I feel that the company's steady diversification is evidence of the importance of research in its development. Even when the merger was agreed in 1926 the name "Farbenindustrie" (dyestuffs industry) was hardly appropriate for the company as a whole. Nitrogen fertilizers were already generating a larger proportion of sales than dyestuffs, and the establishment of new commercial activities based on successful innovations accelerated this trend, making IG Farben one of the most diversified chemical companies by the 1940s.

3.1 Inorganic Chemistry

German-speaking scientists made a huge number of important discoveries in inorganic chemistry, including:[2]

3.1.1. Identifying large numbers of the elements.

3.1.2. Creating the periodic table of the elements.

3.1.3. Making a wide variety of other chemical innovations.

3.1.1 Discoveries of Elements

Once chemists realized in the eighteenth century that chemicals were composed of distinctive elements, there was an international race to purify, characterize, and name as many chemical elements as possible. Several important scientists in that race were in Sweden, France, and the United Kingdom, but arguably the largest share of element discoveries came from scientists in the German-speaking world. The major German-speaking discoveries are summarized below. Note that some elements are listed more than once, if they were independently discovered by different scientists, or first discovered earlier but then characterized in much more detail later.

Carl Wilhelm Scheele (Pomerania, 1742–1786), shown in Fig. 3.1, was the earliest and most successful German-speaking discover of elements. He discovered at least ten elements: hydrogen (1771), nitrogen (1771), oxygen (1771), fluorine (1771), phosphorus (1774), chlorine (1774), manganese (1774), molybdenum (1778), barium (1774), and tungsten (1781).

As illustrated in Fig. 3.2, Martin Klaproth (German states, 1743–1817) discovered six elements: titanium (1795), strontium (1791), zirconium (1789), tellurium (1798), cerium (1803), and uranium (1789).

Friedrich Wöhler (German, 1800–1882) discovered five elements: beryllium (1828), aluminum (1827), silicon (1850), titanium (1850), and yttrium (1828); see Fig. 3.3. He was the first to synthesize several important inorganic molecules such as silane, silicon nitride, and calcium carbide. By synthesizing urea and other organic molecules, he was also one of the founders of organic chemistry and biochemistry.

Robert Bunsen (German, 1811–1899) and Gustav Kirchhoff (German, 1824–1887), shown together in Fig. 3.4, discovered cesium in 1860 and rubidium in 1861 using novel methods of spectroscopic analysis. Bunsen also created the carbon-zinc battery; with Peter Desaga (German, 1812–1879), he created the Bunsen burner.

---

[2] Brock 1993; Bugge 1955; Coffey 2008; Engels et al. 1989; Farber 1961; Ihde 1984; Johnson 1990; Kahlert 2002; Maier 2015; Neufeldt 2003; Partington 1935, 1957, 1964; Scerri 2006; Weeks and Leicester 1968; Werner 2017.

As shown in Fig. 3.5, Jean de Marignac (Swiss, 1817–1894) measured atomic weights with greater precision than others had previously and also discovered three elements: samarium (1880), gadolinium (1880), and ytterbium (1878).

Berta Karlik (Austrian, 1904–1990) and Traude Bernert (Austrian, 1915–1998) discovered short-lived astatine in natural ore samples in 1942; see Fig. 3.5.

Carl Auer von Welsbach (Austrian, 1858–1929, Figs. 3.6 and 6.15), was phenomenally successful on fronts in science, engineering, and business. He discovered four elements: praseodymium (1885), neodymium (1885), ytterbium (1905), and lutetium (1905). He also invented the gaslight mantle (1885), osmium wire (1890), metal filament incandescent lamps (1898), and the flint metal lighter (1903). Based on those inventions and discoveries, he founded the Auergesellschaft, Treibacher Industrie, and Osram companies.

As illustrated in Fig. 3.7, Otto Berg (German, 1873–1939), Walter Noddack (German, 1893–1960), and Ida Tacke Noddack (German, 1896–1978) discovered rhenium and technetium in 1925. In 1934, Ida Tacke Noddack also correctly predicted both neutron-induced uranium fission and methods of producing and purifying neptunium and plutonium, which do not exist naturally (p. 1537).

Other German-speaking discoverers of elements are shown in Figs. 3.8–3.11:

- Hennig Brand (German states, 1630–1692, Fig. 3.8) discovered phosphorus in 1669.

- Clemens Winkler (German, 1838–1904, Fig. 3.8) discovered germanium in 1886.

- Albertus Magnus (German states, 1193–1280, Fig. 3.8) discovered arsenic in 1250.

- Carl Jacob Löwig (German, 1803–1890, Fig. 3.8) discovered bromine in 1825.

- Karl Ernst Claus (Baltic German, 1796–1864, Fig. 3.8) discovered ruthenium in 1844.

- Friedrich Stromeyer (German states, 1776–1835) and Karl Hermann (German states, 1765–1846) discovered cadmium in 1817; see Fig. 3.9.

- Ferdinand Reich (German, 1799–1882) and Hieronymous Theodor Richter (German, 1824–1898) discovered indium in 1863; see Fig. 3.9.

- Franz-Joseph Müller von Reichenstein (Austrian, 1740–1825) discovered tellurium in 1782; see Fig. 3.10.

- Jacques-Louis Soret (Swiss, 1827–1890) and Marc Delafontaine (Swiss, 1838–1911) discovered holmium in 1878; see Fig. 3.10.

- Dirk Coster (Dutch, 1889–1950) and George de Hevesy (Hungarian, 1885–1966) discovered hafnium in 1922; see Fig. 3.10.

- Georgius Agricola, also known as Georg Bauer (German states, 1494–1555, Fig. 3.10), discovered bismuth around 1540. He conducted extensive work on metallurgy.

- Friedrich Ernst Dorn (German, 1848–1916, Fig. 3.11) discovered radon in 1900.

- Gerhard Carl Schmidt (German, 1865–1949, Fig. 3.11) discovered the radioactivity of thorium in 1898; Marie Curie later confirmed that result.

- Kasimir Fajans (Polish, 1887–1975) and Oswald Helmuth Göhring (German, 1889–1915) discovered the first isotope of protactinium in 1913; see Fig. 3.11.

- Otto Hahn (German, 1879–1968) and Lise Meitner (Austrian, 1878–1968) discovered a longer-lived protactinium isotope in 1917; see Fig. 3.11.

German-speaking scientists also discovered all three of the building blocks of atoms: electrons, protons, and neutrons (Section 5.2.3).

Even in English-speaking countries and after so much time, the symbol for the atomic number (the number of protons in the nucleus, or the number of electrons in a neutral atom) is still Z, for the German word "Zahl" or number.

**Carl Wilhelm Scheele
(1742–1786)
discovered
hydrogen (1771),
nitrogen (1771),
oxygen (1771),
fluorine (1771),
phosphorus (1774),
chlorine (1774),
manganese (1774),

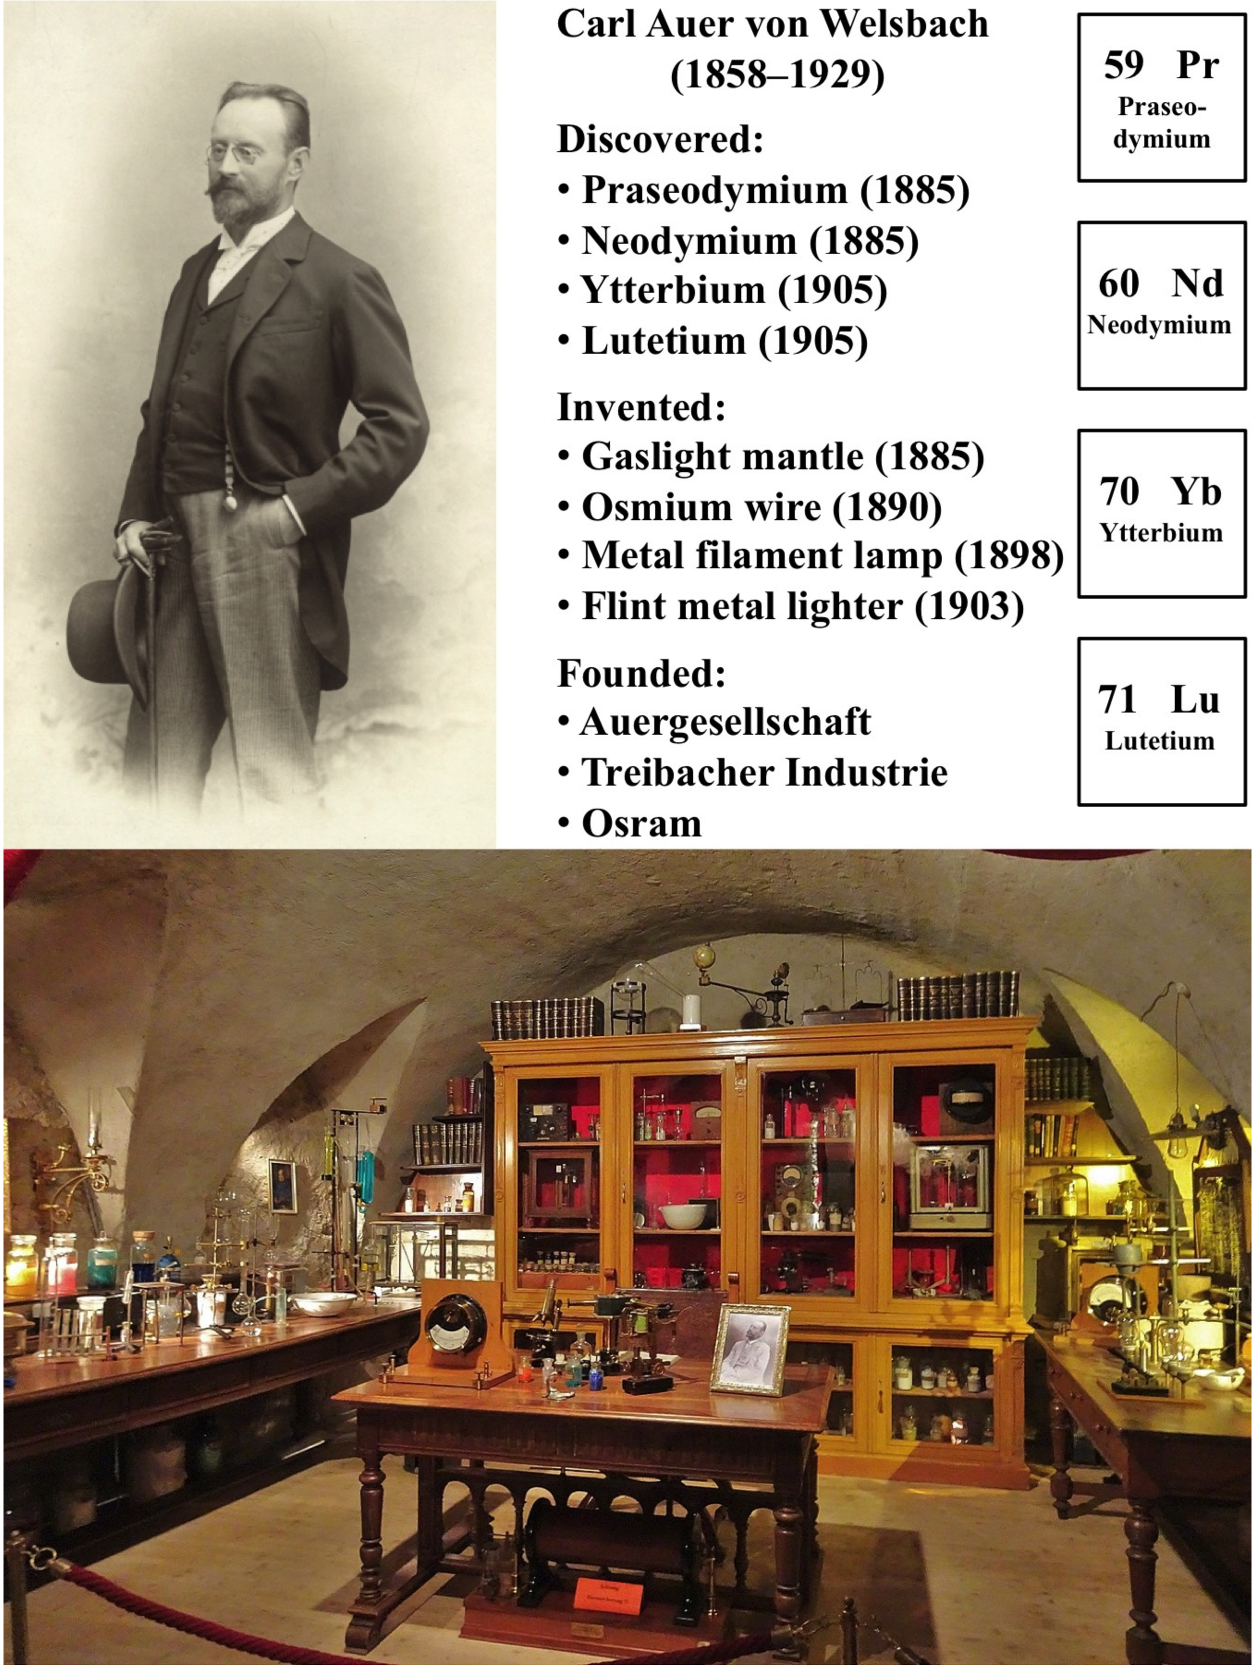
Jean de Marignac (1817–1894)
Measured atomic weights with greater precision
Discovered:
• Samarium (1880)
• Gadolinium (1880)
• Ytterbium (1878)
62 Sm Samarium
64 Gd Gadolinium
70 Yb Ytterbium
Berta Karlik (1904–1990) and Traude Bernert (not shown, 1915–1998)
Discovered astatine (1942)
85 At Astatine

Figure 3.5: Jean de Marignac measured atomic weights with greater precision and discovered samarium, gadolinium, and ytterbium 1878–1880. Berta Karlik and Traude Bernert discovered short-lived astatine in natural ore samples in 1942.



Carl Auer von Welsbach
(1858–1929)
Discovered:
• Praseodymium (1885)
• Neodymium (1885)
• Ytterbium (1905)
• Lutetium (1905)
Invented:
• Gaslight mantle (1885)
• Osmium wire (1890)
• Metal filament lamp (1898)
• Flint metal lighter (1903)

Figure 3.11: Friedrich Dorn discovered radon in 1900. Gerhard Schmidt discovered the radioactivity of thorium in 1898. Kasimir Fajans and Oswald Göhring discovered the first isotope of protactinium in 1913. Otto Hahn and Lise Meitner discovered a longer-lived protactinium isotope in 1917.

3.1.2 Creation of the Periodic Table of the Elements

Johann Wolfgang Döbereiner (German states, 1780–1849), shown in Fig. 3.12, was the first to realize that elements could be grouped by similar chemical properties. Among elements that were known then in 1829, he found three examples of each type, later dubbed triads. He also discovered platinum catalysts and used those to invent an improved lamp, which became widely used as the world's first fluid-filled instant lighter.

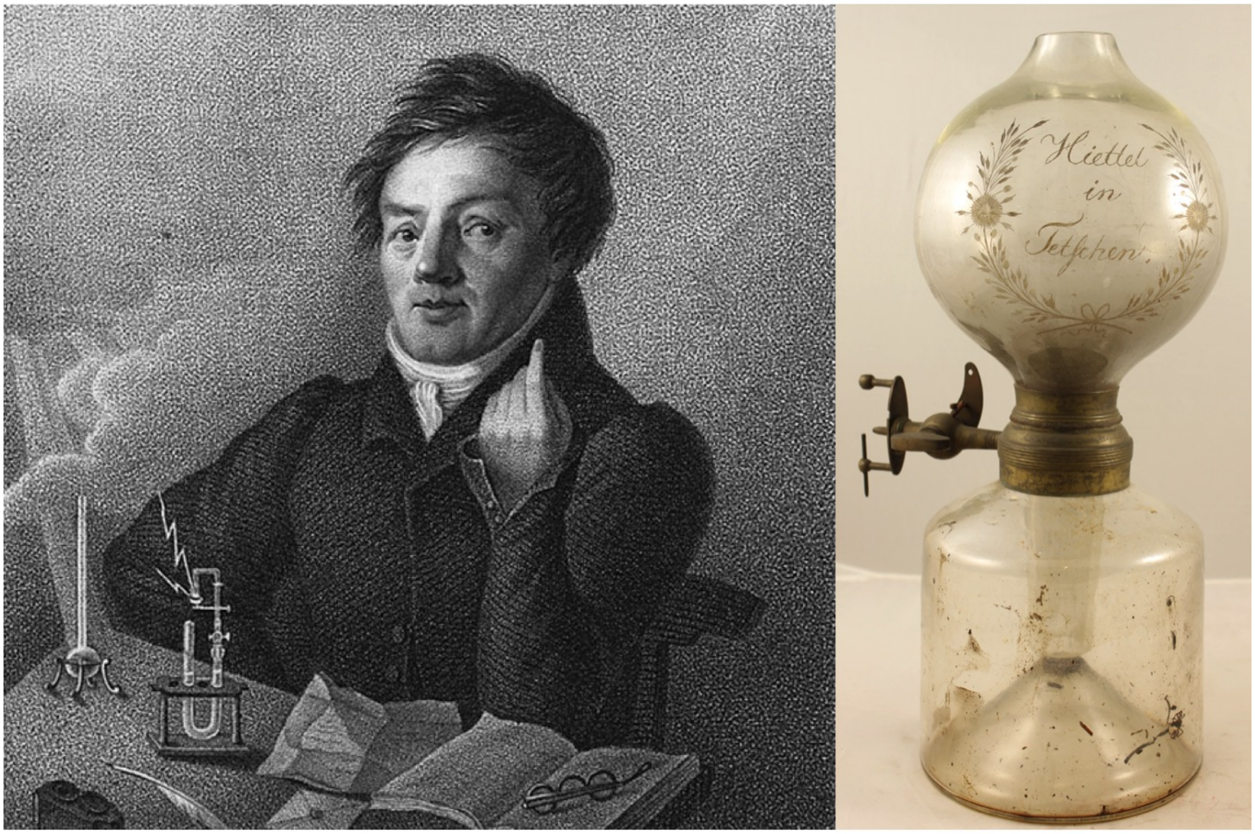
As illustrated in Fig. 3.13, Leopold Gmellin (German states, 1788–1853) expanded Döbereiner's triads into a connected table of known elements in 1843. Some other pioneers of periodic properties of the elements included Max Joseph von Pettenkofer (German, 1818–1901, who also made important contributions to urban hygiene), Peter Kremers (German?, 18??–19??), and Ernst Lenssen (German?, 1837–1870?).

Julius Lothar Meyer (German, 1830–1895) produced the first truly scientific periodic table of the elements in 1862 and published it in his 1864 chemistry textbook, as shown in Fig. 3.14. Meyer's 1864 textbook discussed in detail how the known elements fit into a periodic table that explained all of the measured masses, densities, and valences of the elements (Fig. 3.15). It also predicted new elements that would fill in gaps in the periodic table. Meyer presented data demonstrating the periodic properties of atomic volumes, with peaks corresponding to the beginning of each row of the periodic table. In 1868 he updated his periodic table with additional elements that had been newly discovered (Fig. 3.16).

Dmitri Mendeleev (Russian, 1834–1907) left Russia to study chemistry with Robert Bunsen and Gustav Kirchhoff in Heidelberg in 1860–1861, studied in Switzerland, and then returned to Russia. During his chemistry studies in Germany and Switzerland, Mendeleev almost certainly would have been exposed to the early periodic tables of Döbereiner, Gmellin, and others (though of course the available documents do not record students' discussions from that time). Moreover, it is highly likely that Mendeleev would have heard about the early work of Julius Lothar Meyer, especially since Meyer also studied with Bunsen and Kirchhoff in Heidelberg around the same time that Mendeleev was there. In addition to any personal transfers of information, Meyer's 1864 chemistry textbook that publicly presented and explained the periodic table was widely circulated in Europe, and copies would presumably have been available in Russia after Mendeleev returned home.

After returning to Russia, Mendeleev did not even begin to work on his version of the periodic table until 1869, nine years after his personal immersion in the academic world of German chemistry, and five years after the publication of Meyer's detailed textbook that explained the organization, contents, and scientific evidence for the periodic table. Then Mendeleev did not finalize his version of a periodic table for another decade, until 1879 [Scerri 2006, pp. 105, 112]. Mendeleev never even attempted to offer a credible explanation for how his version of the periodic table resulted from his earlier studies and the earlier researchers. Rather, he quite incredibly claimed that the entire periodic table simply came to him suddenly in a dream, that he had never heard of any earlier versions of the periodic table, and that the entire concept of a periodic table was his alone.

While Mendeleev is widely called the originator of the period table nowadays, the evidence clearly demonstrates that Döbereiner's and Gmellin's work preceded Mendeleev's by decades, and that Julius Lothar Meyer produced and published highly detailed versions of the periodic table backed by large amounts of experimental evidence and accurate predictions years before Mendeleev, even including details that Mendeleev's later table did not. Furthermore, the available evidence suggests that Mendeleev simply plagiarized his "discovery" from the earlier German-speaking scientists.



Johann Wolfgang Döbereiner (1780–1849)
Discovered platinum catalyst (18??)

Döbereiner's lamp

Julius Lothar Meyer (1830–1895)
Periodic table of the elements
(created 1862, published 1864)

Man sieht, dass die erste (resp. die erste und zweite) Differenz in jeder Verticalreihe überall ungefähr 16 ist, ausser zwischen dem noch sehr unsicher bekannten Atomgewichte des Berylliums und dem des Magnesiums. Die beiden folgenden Differenzen schwanken um 46 etwa; die letzte ist annährend doppelt so gross, nämlich 87—90, wenn wir hier wieder von dem noch nicht hinreichend sicheren Atomgewichte des Thalliums absehen, das vielleicht auch (wie bis vor kurzem, nach einer vorläufigen, mit der kaum entdeckten Substanz ausgeführten Bestimmung, das des Caesiums) etwas zu niedrig angenommen ist.

In der Nähe von 46 liegende Differenzen zeigen ferner die Gruppen:

	4 werthig	6 werthig
	Ti = 48	Mo = 92
Differenz =	42	45
	Zr = 90	Vd = 137
Differenz =	47,6	47
	Ta = 137,6	W = 184.

Die vorletzte und die letzte Differenz der ersten Tabelle finden sich noch in nachstehenden Gruppen, von denen nur die letzte Glieder ungleicher Sättigungscapacität enthält.

	4 werthig	4 werthig	4 werthig	2 werthig	
	Mn = 55,1 Fe = 56,0	Ni = 58,7	Co = 58,7	Zn = 65,0	Cu = 63,5
Differ. =	49,2 48,3	45,6	47,3	46,9	44,4
	Ru = 104,3	Rh = 104,3	Pd = 106,0	Cd = 111,9	Ag = 107,94
Differ. =	92,8 = 2.46,4	92,8 = 2.46,4	93,0 = 2.46,5	88,3 = 2.44,2	88,8 = 2.44,4
	Pt = 197,1	Jr – 197,1	Os = 199,0	Hg = 200,2	Au = 196,7

Figure 3.14: Julius Lothar Meyer produced the first scientific periodic table of the elements in 1862 and published it in his 1864 chemistry textbook.

Lothar Meyer's 1864 chemistry textbook showed in detail how the known elements fit into a periodic table that explained all of the measured masses, densities, and valences of the elements. It also predicted new elements that would fill in gaps in the periodic table.

Verlag von Maruschke & Berendt.

123

diejenigen, für welche wenigstens das Atomgewicht als mit Sicherheit festgestellt angesehen werden darf†), ein Doppelsternchen ** dagegen diejenigen, deren Atomgewicht sowohl, als dessen Sättigungscapacität nur aus den stoechiometrischen Zahlen nach Analogien erschlossen werden kann, da weder die Dichte gasförmiger Verbindungen, noch die Wärmecapacität der Atome bekannt ist.

Als einwerthig (oder wenigstens in der Regel einwerthig*) erscheinen die Atome der Elemente:

Wasserstoff	H	= 1	Lithium	*Li	= 7,03
Fluor	Fl	= 19,0	Natrium	*Na	= 23,05
Chlor	Cl	= 35,46	Kalium	*Ka	= 39,13
Brom	Br	= 79,97	Rubidium	**Rb	= 85,4 (Bunsen, Piccard)
Jod	J	= 126,8	Caesium	**Cs	= 133,0 (Johnson und Allen)
Silber	*Ag	= 107,94	Thallium	**Tl	= 204 (Lamy)

Dreiwerthig**) sind:

Bor	B	= 11,0
Stickstoff	N	= 14,04
Phosphor	P	= 31,0
Arsen	As	= 75,0
Antimon	Sb	= 120,6
Wismuth	Bi	= 208,0
Gold	*Au	= 196,7

Zweiwerthig treten auf:

Sauerstoff	O	= 16,00	Zink	Zn	= 65,0
Schwefel	S	= 32,07	Beryllium	**Be	= 9,3 (Awdejew)
Selen	Se	= 78,8			
Tellur	Te	= 128,3	Magnesium	*Mg	= 24,0
Quecksilber	Hg	= 200,2	Calcium	*Ca	= 40,0
Kupfer	*Cu	= 63,5	Strontium	*Sr	= 87,6
Cadmium	*Cd	= 111,9	Baryum	*Ba	= 137,1

---

†) deren Atomgewicht also in einer der in den §§ 20, 21, 28 und 32 mitgetheilten Tabellen enthalten ist.

*) Vergl. § 73.

**) Vergl. übrigens § 72.

124

Vierwerthige Atome scheinen einer grossen Zahl von Elementen zuzukommen, nämlich:

Kohlenstoff	C	= 12,0
Kiesel	Si	= 28,5
Zirkon	Zr	= 90
Titan	Ti	= 48,1
Tantal	**Ta	= 137,6 (H. Rose)
Zinn	Sn	= 117,6

Blei	*Pb	= 207,0	Kobalt	*Co	= 58,74
Palladium	*Pd	= [illegible]	Nickel	*Ni	= 58,74
Ruthenium	**Ru	= 104,3 (Claus)	Mangan	*Mn	= [illegible]
Rhodium	*Rh	= 104,3	Eisen	Fe	= 56,05
Platin	*Pt	= 197,1	Aluminium	Al	= 27,3
Iridium	*Jr	= 197,1	Chrom	*Cr	= 52,6
Osmium	*Os	= 199,0			

Von diesen Elementen werden aber einige, namentlich Pb, Pd, Co, Ni, Mn, Fe und auch Cr, in vielen ihrer Verbindungen zweckmässiger als zweiwerthig betrachtet, wobei man es unentschieden lassen kann, ob in diesen Verbindungen zwei der Verwandtschaftseinheiten des Atomes ungesättigt bleiben oder durch die Verbindung mit einem anderen Atome derselben Art gesättigt werden.†)

Vielleicht findet in manchen Fällen das eine, in anderen das andre statt. Der Isomorphismus des mangansauren und chromsauren Kali mit dem schwefelsauren und selensauren z. B. scheint für die erst erwähnte Möglichkeit zu sprechen.

Einige der als vierwerthig aufgeführten Metalle besitzen vielleicht noch eine schwache fünfte und sechste Affinität, wenn anders die Angaben richtig sind, nach welchen Jr, Os, Mn, und Cr mit mehr als vier Atomen Chlor Verbindungen von freilich sehr geringer Stabilität bilden.

Sie würden in diesem Falle den Uebergang bilden zu den Elementen mit sechsfacher Sättigungscapacität

---

†) Vergleiche § 65 ff das vom Eisenchlorür gesagte, das sich leicht auf entsprechende Verbindungen übertragen lässt.

125

des Atomes.†) Als solche sechswerthige Elemente müssen höchst wahrscheinlich angesehen werden:

Molybdän	* Mo	= 92
Vanadin	** Vd	= 137 (Berzelius)
Wolfram	* Wo	= 184

Ausser den hier besprochenen Elementen sind noch sechs stoechiometrisch untersucht, nämlich Cer, Lanthan, Didym, Niobium, Thorium und Uran. Es scheint mir aber noch zu gewagt, aus deren empirisch gefundenen Mischungsgewichten auf die wahren Atomgewichte derselben und deren Sättigungscapacität Schlüsse zu ziehen.

Ausserdem ist noch die Existenz von fünf oder sechs Elementen nachgewiesen oder behauptet, für welche aber bis jetzt auch das empirische Mischungsgewicht noch nicht festgestellt wurde.

§ 85.

Von der so bestimmten Sättigungscapacität der Atome ausgehend, kann man nun weiter schliessen auf das Molekulargewicht und die Constitution auch nicht gasförmiger Verbindungen, indem man für beide die von den gasförmigen Verbindungen abstrahirten Regeln als gültig betrachtet. Diese Schlüsse haben ebenfalls eine oft ziemlich grosse Unsicherheit. Bleibt man sich aber dessen bewusst, und legt man daher auf diese Folgerungen nicht mehr Gewicht, als sie verdienen, so ist diese Ausdehnung und Verallgemeinerung jener für die Gase geltenden Gesetze durchaus ungefährlich; für die Betrachtung und Darstellung der chemischen Vorgänge aber ist dieselbe von grossem praktischen Werthe.

---

†) Es scheint bemerkenswerth, dass, wo ein Element in verschiedenen Fällen verschiedene Sättigungscapacität zu zeigen scheint, dieselbe in der Regel variirt entweder von 1 : 3 : 5 oder von 2 : 4 : 6. Ersteres z. B. bei Jod und Stickstoff (vergl. § 72 und 73), letzteres bei Blei, Chrom etc. (vergl. a. § 74) Es erinnert dies an die Eigenschaften zusammengesetzter Radicale, § 57.

Figure 3.15: Lothar Meyer's 1864 chemistry textbook showed in detail how the known elements fit into a periodic table that explained all of the measured masses, densities, and valences of the elements. It also predicted new elements that would fill in gaps in the periodic table.

Figure 3.16: Lothar Meyer presented data demonstrating the periodic properties of atomic volumes, with peaks corresponding to the beginning of each row of the periodic table. In 1868 he updated his periodic table with newly discovered elements.

3.1.3 Other Important Contributions to Inorganic Chemistry

Fritz Haber (German, 1868–1934) invented and Carl Bosch (German, 1874–1940) scaled up the Haber-Bosch process for chemically synthesizing ammonia on an industrial scale for fertilizers and explosives (rather than having to rely on limited natural sources, such as harvesting bat guano from caves) [Hager 2008; Stoltzenberg 1994, 2005; Szöllösi-Janze 2015]. See Fig. 3.17. Haber won the 1918 Nobel Prize in Chemistry for this work. Å. G. Ekstrand, President of the Royal Swedish Academy of Sciences, praised Haber's accomplishment [https://www.nobelprize.org/prizes/chemistry/1918/ceremony-speech/]:

> Geheimrat Professor Haber. This country's Academy of Sciences has awarded you the 1918 Nobel Prize for Chemistry in recognition of your great services in the solution of the problem of directly combining atmospheric nitrogen with hydrogen. A solution to this problem has been repeatedly attempted before, but you were the first to provide the industrial solution and thus to create an exceedingly important means of improving the standards of agriculture and the well-being of mankind. We congratulate you on this triumph in the service of your country and the whole of humanity.

In 1962, Rudolf Hoppe (German, 1922–2014) created the first chemical compounds containing noble gases, which had previously been believed to be chemically inert. See Fig. 3.18.

As shown in Figs. 3.19–3.22, many other German-speaking scientists made important contributions to inorganic chemistry:

Richard Abegg (German, 1869–1910, Fig. 3.19) pioneered valence theory (including what is now know as Abegg's rule) and also measured the effects of solutes on freezing point depression, osmotic pressure, and other properties.

Wilhelm Biltz (German, 1877–1943, Fig. 3.19) made careful measurements of many inorganic molecular weights and vapor pressures.

Otto Linné Erdmann (German states, 1804–1869, Fig. 3.19) conducted experiments with nickel and indigo and also measured a number of atomic weights.

Otto Robert Fricke (German, 1895–1950, Fig. 3.19) was especially known for his work with oxide hydrates.

Wilhelm Hampe (German, 18??–19??, Fig. 3.19) studied the properties of metal-halogen compounds.

Siegfried Herzog (German, 1918–2011, Fig. 3.19) conducted research on a variety of compounds containing metals or transition metals.

Kurt Issleib (German, 1919–1994, Fig. 3.20) created and studied a wide range of phosphorus compounds, including phosphorus-containing drug molecules.

Wilhelm Klemm (German, 1896–1985, Fig. 3.20) made important discoveries in many areas of inorganic chemistry, including intermetallic compounds, rare earths, transition elements, oxides, fluorides, and magnetochemistry. As a student, teacher, or collaborator, he worked with many other major inorganic chemists, such as Wilhelm Biltz, Rudolf Hoppe, Eduard Zintl, and others.

Wilhelm Manchot (German, 1869–1945, Fig. 3.20) was especially known for his work on a variety of carbon monoxide reactions, but he also conducted research on silicides and other areas of inorganic chemistry.

Eilhard Mitscherlich (German states, 1794–1863, Fig. 3.20) discovered isomorphism in crystals, experimented with several acids and salts, studied catalysis, and measured the vapor pressures of many volatile compounds.

Paul Pfeiffer (German, 1875–1951, Fig. 3.20) conducted research on ionic compounds and crystals. He discovered salen ligands (complex molecular structures) as well as the Pfeiffer effect of molecules on optical rotation of polarized light.

Carl Friedrich Rammelsberg (German, 1813–1899, Fig. 3.20) studied phosphoric acid and made a large number of important discoveries in chemical mineralogy that were relevant to both geology and industrial mining.

Günther Rienäcker (German, 1904–1989, Fig. 3.21) focused especially on heterogeneous catalysts, their mechanisms, and their applications.

Otto Ruff (German, 1871–1939, Fig. 3.21) was noted for his work in fluorine chemistry, high-temperature chemistry, and several other areas of inorganic chemistry.

Robert Schwarz (German, 1887–1963, Fig. 3.21) conducted important research on the chemistry of silicon, germanium, halogens, and peroxides.

Arthur Simon (German, 1893–1962, Fig. 3.21) harnessed Raman spectroscopy to determine molecular structures. He also developed an electric furnace and a cryostat for chemical experiments.

Georg Ernst Stahl (German states, 1659–1734, Fig. 3.21) conducted some of the first detailed chemical studies of reduction-oxidation reactions and fermentation reactions.

Alfred Stock (German, 1876–1946, Fig. 3.21) studied a number of areas of inorganic chemistry, including boron hydrides, silicon hydrides, beryllium, and mercury toxicity. He created the Stock system (e.g., "iron(II) chloride" for $FeCl_2$) for naming binary chemical compounds that is still in use today.

Erich Thilo (German, 1898–1977, Fig. 3.22) created and studied novel inorganic polymers composed of silicates, as opposed to more conventional carbon-based polymers.

Hans von Wartenberg (German, 1880–1960, Fig. 3.22) developed techniques and compiled a large amount of important data regarding high-temperature chemistry. He also did important work in silicon chemistry.

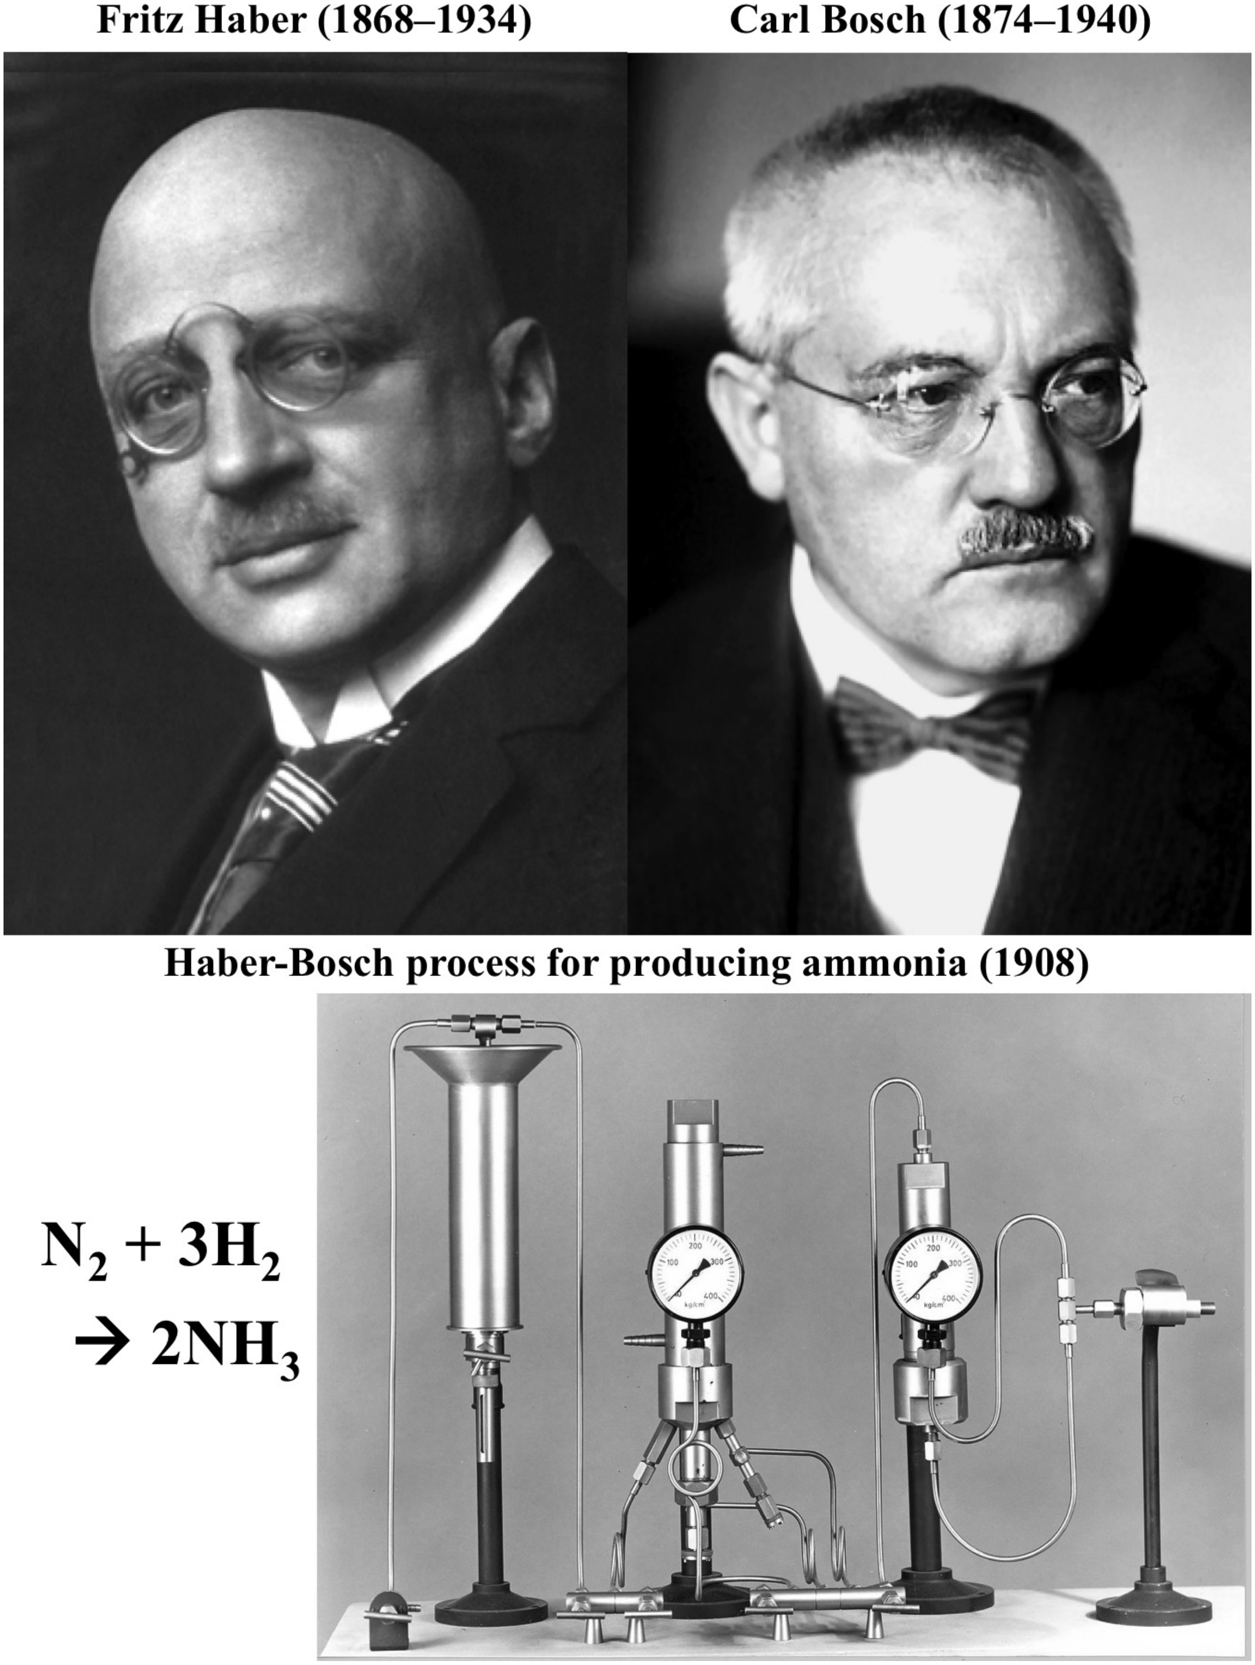
Alfred Werner (Swiss, 1866–1919, Fig. 3.22) won the Nobel Prize in Chemistry in 1913 for his discoveries regarding the coordination chemistry of bonding and stereochemistry in inorganic molecules. T. Nordström, President of the Royal Swedish Academy of Sciences, explained the importance of Werner's work [https://www.nobelprize.org/prizes/chemistry/1913/ceremony-speech/]:

> The number of atoms or groups of atoms which can be linked in a first sphere with the elementary atom functioning as centre, or which in other words can be coordinated into complex radicals under direct linkage with an atom, Werner calls the coordination number. This is a dearly defined numerical concept which is superior to other numerical

> concepts designed to characterize affinity saturation in that it is to some extent independent of the nature and valence of the interconnected elementary atoms, in so far as it has the same value for the great majority of elements. Only two such numerical values have been demonstrated as yet, i.e. four for some elements, and six for the others.
>
> By this approach of which only some principal characteristics can be mentioned here, Werner explains the structure and origin of complex inorganic compounds. By widening and deepening the concept of valence which incorporates his view he has succeeded in bringing atomistic and molecular compounds together under a common point of view. He has drawn a large number of diverse compounds into the range of his comprehensive expert mental work and has thereby been able to establish a uniform system for large groups of inorganic compounds. Werner's approach has also exerted significant influence on research in organic chemistry.
>
> Werner's theory has been supported in an extremely important and valuable manner by the stereochemical researches which he carried out as a sideline, mostly in connection with his work on the constitution of chemical compounds.
>
> By virtue of his theory of the asymmetrical carbon atom, van't Hoff became the real founder of the stereochemistry of organic compounds, and it is Werner's indisputable merit to have introduced this approach to inorganic chemistry as well. Even in his earlier investigations into certain metal ammonias he was able to show that numerous cases of isomerism in complex cobalt and platinum compounds could only be satisfactorily explained by steric approach. For complex radicals of a certain type he put forward a steric theory—the octahedron theory—which predicted that certain of these compounds must occur in two stereoisomeric forms, a prediction which has been confirmed by experiment. By far the greatest interest in this field attaches also to the discovery he made in the last few years, that certain cobalt, chromium, iron, and radium compounds with an asymmetrical metal atom in the complex radical can be divided into two forms which behave like mirror images and show differences of the same kind as those in organic mirror-image isomers, i.e. they are optical antipodes of each other. This discovery is a splendid support for Werner's theory. It has been called the most important discovery in chemistry in recent times, and his stereochemical work makes him the founder of inorganic stereochemistry.
>
> As to Werner's research work as a whole we can with good reason agree with the remark of an eminent research worker, that Werner's theoretical and experimental work in inorganic chemistry has opened up new paths of chemical research and is of positively revolutionary significance. It is substantially his researches which have during the last few decades set the trend of development in inorganic chemistry and have newly inspired this branch of science which had been somewhat neglected during the last quarter of the 19th century, by giving it new impulses which have borne fruit in numerous different special studies by various research workers.

Lothar Wöhler (German, 1870–1952, Fig. 3.22) spent his career studying oxidative reactions for explosives, catalysts, and other applications.

Eduard Zintl (German, 1898–1941, Fig. 3.22) made important discoveries regarding intermetallic compounds; his name remains associated with Zintl phases and Zintl ions.



Fritz Haber (1868–1934)
Carl Bosch (1874–1940)
Haber-Bosch process for producing ammonia (1908)

3.2 Organic Chemistry

German-speaking scientists dominated the development of organic chemistry, or the chemistry of molecules that contain significant numbers of carbon atoms.[3] Organic chemistry is especially important since carbon-rich molecules include everything from biological molecules and pharmaceuticals to synthetic polymers and dyes.

This section covers some of the German-speaking creators and their creations that were involved in:

3.2.1. Synthetic dyes and the origins of organic chemistry

3.2.2. General organic chemistry

3.2.3. Organometallic chemistry

3.2.4. Synthetic fuels

3.2.5. Liquid crystals

3.2.6. Technology transfer out of the German-speaking world

3.2.1 Synthetic Dyes and the Origins of Organic Chemistry

One of the strongest motivations for the development of organic chemistry in the German-speaking world was the creation of synthetic fabric dyes that could be cheaper than natural dyes and could come in a greater variety of colors. That industry was quite lucrative, yet it also led to the generation of many would-be dyes that had pharmaceutical, explosive, or other desirable properties. All of those applications drove the need to understand the science of organic molecules and reactions, and to develop methods of synthesizing and mass-producing any desired organic molecule.

Ulrich Wengenroth, a scientific historian at the Deutsches Museum in Munich, summarized the importance of the German-speaking world for organic chemistry, and vice versa [Landes et al. 2010, pp. 290–291]:

> The showcase of German science-based industry was undoubtedly organic chemistry. From the 1880s until well after World War II German companies held a commanding position in most products based on carbon hydrates, especially when it came to high-value products like pharmaceuticals. The success story began with synthetic dyestuffs in the 1880s. Although the first synthetic dyestuffs were created in France and England, the latter in a laboratory set up by a student of the German chemist Liebig, it was German firms, supported by academic chemists from universities and engineers from

> polytechnics, that turned synthetic dyestuffs into an industry with a highly methodical and scientific approach. The main strategy was always the same: analyze a natural product and then find ways to synthesize it cheaply from the tar derivatives the heavy industries and gasworks would abundantly supply. The overabundant supply of first-rate human capital for industrial research, plus the additional incentive of not having access to natural resources for colonies, created a situation that proved to be immensely fortunate. Only the Swiss chemical industry, also with a good supply of academically trained scientists and no colonies, could match the progress of German organic chemistry. It was one of the first examples after the Industrial Revolution when the absence of natural resources proved to be beneficial. Apart from the availability of highly qualified human capital, the German dyestuffs industry benefited from having hit a treasure trove of potential products, and the most innovative entrepreneurs were smart enough to see and fully utilize that potential.
>
> Serendipity had it that hydrocarbons are at the root of three major product families: dyestuffs, synthetic materials, and pharmaceuticals. In looking for one, chemists would inevitably find the others. They just had to find out what the properties of the respective stuff were they had hit upon. This was done by massive testing on a hitherto unprecedented scale by hundreds of professionals in the laboratories of the big three (Hoechst, Bayer, BASF) of the German chemical industry. In the words of Carl Duisberg, head of Bayer, there was "nowhere any trace of a flash of genius" in the labs, just academic toil and screening. Eventually his company found more than 10,000 synthetic dyestuffs before the eve of World War I, 2,000 of which were marketed. At the same time they had hit on dyestuffs that wouldn't dye but could cure ills. Many twentieth-century drugs are "failed dyes," Valium being just the most profitable among them. Next to drugs a host of synthetic materials was found "on the way" and gave rise to ever more scrutiny when laboratories were testing newly synthesized chemicals.
>
> Charts of tar-based products show a wide spectrum from explosives to anesthesia, Bakelite, and a number of synthetic dyestuffs and their intermediates. [...] It took the German chemical industry's competitors decades and the scrapping of all property rights in the wake of the wars slowly to erode the position it had built by the turn of the century.

Two of the most important founders of organic chemistry were Friedrich Wöhler and Justus von Liebig, who were friends and research collaborators throughout most of their careers. They also educated and inspired a huge number of younger chemists who went on to make major discoveries themselves.

Friedrich Wöhler (German, 1800–1882), shown in Fig. 3.23, synthesized urea, discovered compound radicals, and made other discoveries that helped to establish the field of organic chemistry. As the years went by, he spent more and more of his time educating and mentoring chemistry students, to whom he was quite devoted and helpful. Oxford University's *Biographical Dictionary of Scientists* summarized some of his research history [Porter 1994, pp. 731–732]:

> In Wöhler's first research in 1827 he isolated metallic aluminium by heating its chloride with potassium; he then prepared many different aluminium salts. In 1828 he used the same procedure to isolate beryllium. Also in 1828 he carried out the reaction for which he is best known. He heated ammonium thiocyanate—a crystalline, inorganic substance—and converted it to urea (carbamide), an organic substance previously obtained only

> from natural sources. Until that time there had been a basic misconception in scientific thinking that the chemical changes undergone by substances in living organisms were not governed by the same laws as were inanimate substances[...]
>
> Wöhler worked with Justus von Liebig on a number of important investigations. In 1830, they proved the polymerism of cyanates and fulminates, and two years later announced a series of studies of benzaldehyde (benzenecarbaldehyde) and the benzoyl (benzenecarboxyl) radical. In 1837, they investigated uric acid and its derivatives. Wöhler also discovered quinone (cyclohexadiene-1,4-dione), hydroquinone or quinol (benzene-1,4-diol) and quinhydrone (a molecular complex composed of equimolar amounts of quinone and hydroquinone).
>
> In the inorganic field Wöhler isolated boron and silicon and prepared silicon nitride and hydride. He prepared phosphorus by the modern method, and discovered calcium carbide and showed that it can be reacted with water to produce acetylene (ethene) [...]

Justus von Liebig (German, 1803–1873) collaborated with Wöhler for much of his career, for example in discovering compound radicals. As illustrated in Fig. 3.24, he taught large number of students in his laboratory, creating generations of later chemists. The *Encyclopedia Britannica* described his research [EB 2010]:

> [T]he radical theory that Liebig did much to develop was the first major attempt at systematization in organic chemistry.
>
> Liebig's studies in organic chemistry were greatly aided by the simple method he developed for the analytical determination of carbon and hydrogen. He also developed a method for the analytical determination of halogens, published important work on polybasic organic acids, and did much to support the hydrogen theory of acids. [...]
>
> After 1838 Liebig's interest shifted from pure organic chemistry to the chemistry of plants and animals. He made a large number of analyses of tissues and body fluids and carried out a study of the nitrogenous products of the animal organism. [...] He [...] showed that plants took carbon dioxide, water, and ammonia from the air and soil.

As shown in Fig. 3.25, Otto Unverdorben (German, 1806–1873), Friedlieb Ferdinand Runge (German, 1795–1867), Carl Fritzsche (German, 1808–1871), and August Wilhelm von Hofmann (German, 1818–1892) synthesized aniline, which can be chemically modified to produce a wide variety of colored dyes, explosives, and drugs. In 1820, Runge was also the first scientist to extract and identify caffeine. Even the American Council of Learned Societies praised von Hofmann's contributions and impact [ACLS 2000, pp. 432–433]:

> He obtained his doctorate in 1841 and taught at the University of Bonn. In 1845, under the sponsorship of Prince Albert, he went to England, where he became director of the Royal College of Chemistry, London. He stayed there until 1865, when he was given the chemistry chair at the University of Berlin. [...]
>
> Hofmann's influence on British and German chemistry was profound. He was responsible for continuing the method of science teaching by laboratory instruction that had been

> established and popularized by Liebig at Giessen and for transporting it to England and Berlin. He created his own school of chemists who were interested primarily in experimental organic chemistry and its industrial applications. Much of his experimentation had to do with coal tar and its derivatives. In 1843 he established that many substances obtainable from coal tar naphtha and its derivatives were all of a single nitrogenous base, aniline. His discoveries—and those of his school—laid the foundation for the coal tar products industries. He also did important work on the chemistry of dyes.

Heinrich Caro (German, 1834–1910), Carl Gräbe (German, 1841–1927), and Carl Theodore Liebermann (German, 1842–1914), shown in Fig. 3.26, synthesized alizarin red dye in 1868.

Adolf von Baeyer (German, 1835–1917), Karl Heumann (German, 1850–1894), Johannes Pfleger (German, 1867–1957), and Rudolf Knietsch (German, 1854–1906) synthesized indigo dye. Adolf von Baeyer won the Nobel Prize in Chemistry in 1905. See Fig. 3.27. Professor A. Lindstedt, President of the Royal Swedish Academy of Sciences, explained the importance of von Baeyer's work [https://www.nobelprize.org/prizes/chemistry/1905/ceremony-speech/]:

> Among the living research workers who have contributed directly or indirectly to the unique development of the tar-dyestuff industry the place of honour goes to the Professor at Munich University, Adolf von Baeyer, for his researches into the composition of indigo as well as into the triphenyl methane dyestuffs.
>
> Indigo, the gorgeous pigment of the indigo plant, has been considered the most important of all organic pigments on account of its beauty and colour fastness, and the annual tribute which the West used to pay India for it amounted to a very considerable sum. To reproduce the pigment by synthetic methods and make it more easily obtainable was therefore an exceptionally inviting task for chemical research.
>
> The complex and unique composition of indigo, however, made this also one of the hardest of tasks. Here there could be no question of one of those casual discoveries, which by happy accident seem to achieve half the work. Years of work were required for even von Baeyer's acumen and experimental skill to achieve the necessary insight into the pigment's chemical composition and to be able to manufacture it from simpler constituents. Even after the purely scientific part of the work had been completed it still took a number of years to make the results obtained from research applicable to technology. [...]
>
> Simultaneously with his analyses within the indigo group, analyses moreover which exerted a far-reaching influence upon the development of organic chemistry and directed research into new channels, von Baeyer was active with no less success in another sphere of the chemistry of organic dyestuffs. The stimulus was given by his discovery of a new group of beautifully coloured compounds, the so-called phthaleins, of which only the eosin pigments, highly important to industry, and the rhodamin dyes derived from them, may have particular mention here. In a series of masterly experiments von Baeyer demonstrated several years ago the chemical nature of the phthaleins and showed that, just like the already known rosaniline dyes, they may be classified as derivatives of the hydrocarbon triphenylmethane. In recent years—more exactly, from 1900 on—von Baeyer has resumed his work on triphenylmethane, and from this a new conception

> of the chemical composition of pigments and in general of the connection between the optical properties of organic substances and their interior atomic structure has been to a high degree prepared.
>
> The dyestuffs studied by von Baeyer belong to the main category of organic substances usually classified under the name of aromatic compounds, which differ decisively from the other organic substances—the so-called aliphatic or fatty acid series—both in their properties and in their behaviour in reaction. In fact this difference has been considered so great that it has caused the division of the whole of organic chemistry into two separate halves: the chemistry of aliphatic, and of aromatic substances. Nevertheless, one of the main tasks of scientific research is to try to bridge the gulfs dividing different sciences, or different branches of the same science. In this respect, too, von Baeyer has carried out notable work in his research, remarkable alike from the experimental as well as from the theoretical point of view, on the so-called hydroaromatic compounds. With these compounds, he has found the transitional form between the two main series just mentioned and by application of the new conception and the new method to the terpenes and the species of camphor occurring in nature and also important for technology, he has opened up fields for synthetic work which were previously inaccessible.

There were many other German-speaking chemists who developed thousands of other artificial dyes. Peter Griess (German, 1829–1888), Otto Nikolaus Witt (German/Swiss, 1853–1915), and Paul Friedländer (German, 1857–1923), depicted in Fig. 3.28, are just a few additional examples of important dye creators.

3.2.2 General Organic Chemistry

An enormous number of German-speaking scientists made important contributions to organic chemistry. This section can only briefly mention some examples (Figs. 3.29–3.47). For simplicity, they are mainly in alphabetical order.

Karl von Auwers (German, 1863–1939, Fig. 3.29) received his Ph.D. under August Wilhelm von Hofmann and in turn was the doctoral adviser of Georg Wittig and Karl Ziegler. He is best remembered for developing Auwers synthesis in 1908.

Eugen Bamberger (German, 1857–1932, Fig. 3.29) also received his Ph.D. under August Wilhelm von Hofmann. He discovered the Bamberger rearrangement in 1894.

Ernst Beckmann (German, 1853–1923) developed the Beckmann rearrangement (1886), shown in Fig. 3.30, which later proved extremely useful for making Nylon and several important drugs. He also invented the Beckmann freezing-point apparatus and thermometer.

Friedrich Beilstein (German, 1838–1906, Fig. 3.30) created the encyclopedic *Beilstein's Handbook of Organic Chemistry* in 1881 and continued to update its collection of organic molecules and information during his lifetime. Other chemists have continued to update and maintain *Beilstein's Handbook* to this day.

Ernst Bergmann (1903–1975, Fig. 3.31) received his Ph.D. under Wilhelm Schlenk at the University of Berlin in 1927 and conducted important research in organic and fluorine chemistry. Soon after the founding of the modern nation of Israel, he became the head scientist of the Israeli program to develop nuclear weapons. (This is another example of German-speaking scientists being responsible for developing nuclear weapons in several different countries.)

Julius von Braun (Polish/German, 1875–1939, Fig. 3.31) was a doctoral student of Otto Wallach and made several discoveries such as the von Braun reaction and the Rosenmund-von Braun reaction.

Julius Bredt (German, 1855–1937, Fig. 3.31) determined the structure of camphor and is also known for Bredt's rule and the Bredt distributor.

Hans Theodor Bucherer (German, 1869–1949, Fig. 3.31) received his Ph.D. under Johannes Wislicenus and went on to discover the Bucherer reaction, Bucherer carbazole synthesis, and the Bucherer-Bergs reaction.

George Büchi (German, 1921–1998, Fig. 3.31) is especially remembered for his studies of photochemical organic reactions.

Ernst Büchner (1850–1924, Fig. 3.31) spent his career working in organic chemistry and developed the Büchner flask and the Büchner funnel, both of which are now widely used for filtration in chemistry and biology experiments.

Robert Bunsen (German, 1811–1899, Fig. 3.32) conducted research in organic chemistry in addition to his well-known work in inorganic chemistry. He worked with organic arsenides, discovered an antidote for arsenic poisoning (iron oxide hydrate) and studied organic photochemistry.

Rainer Ludwig Claisen (German, 1851–1930, Fig. 3.33) developed many incredibly useful experimental methods that have been widely employed in organic chemistry ever since, including Claisen condensation, the Claisen reaction, the Claisen rearrangement, the Claisen flask, etc.

Rudolf Criegee (German, 1902–1975, Fig. 3.32) studied the oxidation of organic molecules and the properties of cyclic reactions. He discovered the Criegee rearrangement and the Criegee intermediate.

Theodor Curtius (German, 1857–1928, Fig. 3.32) discovered the Curtius rearrangement and several novel molecules, including hydrazine, an extremely important rocket fuel.

Walter Dieckmann (German, 1869–1925, Fig. 3.33) is most famous for developing Dieckmann condensation, a step that ever since then has been widely utilized in the synthesis of organic molecules.

Otto Diels (German, 1876–1954) and Kurt Alder (German, 1902–1958) developed Diels-Alder reactions (1928), which are very useful for producing polymers and other complex organic molecules. They both won the Nobel Prize in Chemistry in 1950. See Fig. 3.34. Professor A. Fredga of the Nobel Committee for Chemistry explained the importance of their work [https://www.nobelprize.org/prizes/chemistry/1950/ceremony-speech/]:

> Professor Diels, Professor Alder. More than two decades have passed since the day when you sent in the first paper on "Syntheses in the Hydroaromatic Series" to the Editor of the *Annals*. Much has happened since then—in Science, as well as in the world.
>
> The reciprocal addition of the unsaturated compounds was at that time still somewhat mysterious. The chemistry of the high polymer compounds belonged for the most part to the future. You found it necessary to stress that the new substances which you obtained so easily were not molecular compounds but were really new molecules, stable and firmly bonded. New simple bonds had come into being of the old, well-known kind. This identification has paved the way to a right understanding of the polymerization phenomena of the unsaturated compounds, and through it you have very greatly advanced the development of high polymer chemistry and technics.
>
> In this treatise you have even indicated how highly promising the consequences of the low molecular compounds were for the future of chemistry. In the past years the synthesis of dienes has, to be sure, achieved more than you could either foresee or predict when you wrote your paper. But the general trend, the prophetic leading ideas are already to be found in it.
>
> You mention there the possibilities for discussion of several theoretically interesting questions concerning the forces of attraction in polycyclic systems. You also mention the practical consequences. The possibility of the synthetic production of complicated natural substances or of compounds similar to them is, in your view, immediately in prospect. Finally you indicate the possibility that this astonishingly rapid and smoothly running reaction could also play a significant part in the processes of Nature.
>
> Since 1928 the synthesis of dienes has been developed in various directions by numerous workers, and its significance has become more and more obvious. You have yourselves, partly together, partly independently, worked with great success in the field you have

> opened up. The external circumstances were not always of the best for reasons which we all know. We have been told that you, Professor Diels, were in the past years unable to do any experimental work. And yet your thoughts played keenly upon scientific problems and we hope that you will soon have the opportunity of approaching the problems experimentally as well. You, Professor Alder, in spite of limited facilities for work, are again fully active. During the past year you have, by your splendid work on the steric and energetic conditions in the polycyclic systems, successfully maintained your position as the leading research worker in this field.

André Dreiding (Swiss, 1919–2013, Fig. 3.32) developed Dreiding stereomodel kits for physically building and showing organic molecular structures.

Richard August Carl Emil Erlenmeyer (German, 1825–1909, Fig. 3.32) had a long career working in many different areas of organic chemistry and biochemistry, but he is best remembered for the Erlenmeyer flask and the Erlenmeyer rule.

Hermann von Fehling (1812–1885, Fig. 3.32) is famous for developing Fehling's solution for detecting sugars, which has since been widely used everywhere from public school classrooms to hospital laboratories.

Hermann Emil Fischer (German, 1852–1919, Fig. 3.35) is remembered for many innovations such as Fischer esterification and Fischer projection. He won the Nobel Prize in Chemistry in 1902 for his work on the synthesis of sugars and purines. Professor Hj. Théel, President of the Swedish Royal Academy of Sciences, praised his research [https://www.nobelprize.org/prizes/chemistry/1902/ceremony-speech/]:

> With surprisingly acute judgement and with brilliant discernment in choosing his ways and means Fischer not only reproduced synthetically natural grape- and fruit-sugars, but also some thirty other sugars and an abundance of closely related compounds. Whereas of the naturally occurring, simple sugars only those with 5-6 carbon atoms have been found, Fischer synthesized a continuous series containing from 2 to 9 carbon atoms. Furthermore, by his elegant method of making glucosides artificially, he has also added to the achievements of organic synthesis this group which is so extraordinarily important for vegetable physiology. [...]
>
> Even since 1776 when Scheele found uric acid in urinary calculus, several substances closely related to it such as xanthine, adenine and guanine, etc. have been detected in animal secretions. The same group additionally includes theobromine, theophylline and caffeine which occur in the vegetable kingdom and constitute the stimulants in our staple beverages cocoa, coffee and tea. With the keen perception of the excellent scientist and a masterly technique Professor Fischer brought order and clarity to this field as well. He demonstrated that all those substances are derivatives of the same parent substance, purine, which he had discovered. He successfully prepared them from one another and from simpler constituents in such a way that here, too, the synthesized chain goes back to inorganic carbon, hydrogen and oxygen, and besides these he prepared a large number of new, closely related substances so that the purine derivatives studied by Fischer must now number about 150. The intrinsic composition of each has been fully determined.

Wilhelm Rudolph Fittig (German, 1835–1910, Fig. 3.35) worked in several areas of organic chemistry during his career and discovered several new molecules and new types of organic reactions. His name is most closely associated with the Fittig reaction for the synthesis of alkylbenzene molecules.

Hermann Frasch (1851–1914, Fig. 3.35) spent most of his career using organic chemistry to improve processes in oil refining.

Karl Fries (German, 1875–1962, Fig. 3.35) received his Ph.D. under Theodor Zincke and is best known for discovering the Fries rearrangement of phenolic ester molecules.

Ludwig Gattermann (1860–1920, Fig. 3.35) wrote a widely used textbook of experimental methods in organic synthesis. He also discovered new methods such as the Gattermann reaction.

Carl Glaser (German, 1841–1935, Fig. 3.35) developed Glaser coupling, which was later used to synthesize indigo dye and other important organic molecules.

Irma Goldberg (Russian but educated in Switzerland and worked in Switzerland and Germany, 1871–<1939, Fig. 3.36) worked with and married Fritz Ullmann. She developed several synthetic dye molecules and is remembered for the Goldberg amidation reaction.

Fritz Haber (German, 1868–1934, Fig. 3.36) studied carbon-carbon and carbon-hydrogen bond strengths and other topics in organic chemistry, in addition to his better known work on ammonia synthesis in inorganic chemistry (for which he won the 1918 Nobel Prize in Chemistry—see p. 447).

Arthur Hantzsch (German, 1857–1935, Fig. 3.36) developed Hantzsch pyridine synthesis and Hantzsch pyrrole synthesis.

Kurt Hoesch (German, 1882–1932, Fig. 3.36) focused on the synthesis of phenylketone molecules and developed the Hoesch reaction for that purpose.

Erich Hückel (German, 1896–1980, Fig. 3.36) is famous for the Hückel molecular orbital theory, as well as his contributions to physical chemistry such as the Debye-Hückel theory for electrolysis.

Rolf Huisgen (German, 1920–, Fig. 3.36) studied the reaction mechanisms involved in each step of synthesizing organic molecules, and personally developed the Huisgen reaction.

Claire Hunsdiecker (German, 1903–1995, Fig. 3.37) and Heinz Hunsdiecker (German, 1904–1981, Fig. 3.37) received their Ph.D.s in chemistry, married, and spent their lives conducting research in organic chemistry. They are best known for the Hunsdiecker reaction.

Oskar Georg Friedrich Jacobsen (German, 1840–1889, Fig. 3.37) studied the distillation and components of coal tar, discovered the Jacobsen rearrangement, and pioneered the field of marine chemistry.

Karl Kastner (1783–1857, Fig. 3.37) helped to establish chemistry as a proper academic field of study. He taught Justus von Liebig, who in turn educated a huge number of important chemists.

August Kekulé (German, 1829–1896) figured out the chemical bonds and structure of benzene (1865) and other organic molecules; see Fig. 3.38.

Heinrich Kiliani (German, 1855–1945, Fig. 3.37) studied digitalis and carbohydrate chemistry, and developed (along with Emil Fischer) the Kiliani-Fischer synthesis of sugar molecules.

Emil Knoevenagel (German, 1865–1921, Fig. 3.37) focused on experimental methods of synthesizing organic molecules and is remembered for the Knoevenagel condensation reaction.

Ludwig Knorr (German, 1859–1921, Fig. 3.39) developed processes such as Knorr quinoline synthesis and Knorr pyrrole synthesis, and synthesized phenazone, an aspirin-like drug molecule (p. 269).

Hermann Kolbe (German, 1818–1884, Fig. 3.39) helped to formalize the field of organic chemistry and coined the term "synthesis." His name is associated with Kolbe electrolysis, Kolbe nitrile synthesis, and the Kolbe-Schmitt reaction.

Wilhelm Körner (1839–1925, Fig. 3.39) studied many aromatic compounds as well as biochemical molecules from plants.

Albert Ladenburg (1842–1911, Fig. 3.39) purified scopolamine (which is now used to treat nausea) and synthesized other alkaloid drug molecules.

Carl Mannich (German, 1877–1947, Fig. 3.39) worked in several different areas of organic chemistry, including keto bases and alcohol bases, and remains best known for the Mannich reaction.

Hans Meerwein (German, 1879–1965, Fig. 3.39) developed or determined the mechanisms of several key organic synthesis reactions, leading to his name being associated with methods such as Meerwein arylation, Meerwein's salt, Meerwein-Ponndorf-Verley reduction, and the Wagner-Meerwein rearrangement.

Jakob Meisenheimer (German, 1876–1934, Fig. 3.40) synthesized and determined the structures of a number of organic molecules, most notably the class of molecules that are now known as the Meisenheimer complex.

Julius Lothar Meyer (German, 1830–1895, Fig. 3.40) made his greatest contribution to chemistry by developing the periodic table of the elements (p. 444), but he also did important work in organic chemistry, such as studying the structure of benzene.

Karl Meyer (German, 1899–1990, Fig. 3.40) did fundamental research on polysaccharide molecules such as hyaluronan, a component of many human cells and some bacteria.

Kurt Hans Meyer (German, 1883–1952, Fig. 3.40) received his Ph.D. under Arthur Hantzsch and studied a wide variety of organic reactions over the course of his career.

Viktor Meyer (German, 1848–1897, Fig. 3.40) worked in both organic and inorganic chemistry. Among other accomplishments, he discovered thiophene and developed the Viktor Meyer apparatus for measuring vapor densities.

Eilhard Mitscherlich (German, 1794–1863, Fig. 3.40) did important research in the fields of crystallography, inorganic chemistry, and organic chemistry. In organic chemistry, he is best known for his experiments on benzene derivatives.

Costin D. Nenitzescu (Romanian, educated in Switzerland and Germany, 1902–1970, Fig. 3.41) studied under Hans Fischer and went on to a long career synthesizing and identifying organic molecules. Nenitzescu synthesis is named for him.

George Olah (Oláh György, Hungarian, 1927–2017, Fig. 3.41) won the Nobel Prize in Chemistry in 1994 for his work on carbocations. Professor Salo Gronowitz of the Royal Swedish Academy of Sciences explained his discoveries [https://www.nobelprize.org/prizes/chemistry/1994/ceremony-speech/]:

> Because it was not possible to detect carbocations with spectroscopic methods, different scientists interpreted their experiments differently, and a scientific feud took place in organic chemistry during the 1960s and 1970s.
>
> Through a series of brilliant experiments Professor George Olah solved the problem. He created methods to prepare long-lived carbocations in high concentrations, which made it possible to study their structure, stability and reactions with spectroscopic methods. He achieved this by using special solvents, which did not react with the cations. He observed that in these solvents at low temperatures, carbocations could be prepared with the aid of superacids, acids eighteen powers of ten stronger than concentrated sulfuric acid. Through Olah's pioneering work he and the scientists who followed in his footsteps could obtain detailed knowledge about the structure and reactivity of carbocations. Olah's discovery resulted in a complete revolution for scientific studies of carbocations, and his contributions occupy a prominent place in all modern textbooks of organic chemistry.
>
> Olah found that there are two groups of carbocations, the trivalent ones called carbenium ions, in which the positive carbon atom is surrounded by three atoms, and those in which the positive carbon is surrounded by five atoms, called carbonium ions. The disputed existence of these penta-coordinated carbocations was the reason for the scientific feud. By providing convincing proof that penta-coordinated carbocations exist, Olah demolished the dogma that carbon in organic compounds could at most be tetra-coordinated, or bind a maximum of four atoms. This had been one of the cornerstones of structural organic chemistry since the days of Kekulé in the 1860s.
>
> Olah found that the superacids were so strong that they could donate a proton to simple saturated hydrocarbons, and that these penta-coordinated carbonium ions could undergo further reactions. This fact has contributed to a better understanding of the most important reactions in petrochemistry. His discoveries have led to the development of methods for the isomerization of straight chain alkanes, which have low octane numbers when used in combustion engines, to produce branched alkanes with high octane numbers. Furthermore, these branched alkanes are important as starting materials in industrial syntheses. Olah has also shown that with the aid of superacids it is possible to prepare larger hydrocarbons with methane as the building block. With superacid catalysis it is also possible to crack heavy oils and liquefy coal under surprisingly mild conditions.

Wilhelm Ostwald (1853–1932, Fig. 3.41) made a number of important contributions in organic chemistry, catalytic chemistry, and physical chemistry. He won the Nobel Prize in Chemistry in 1909 (p. 913).

Hans von Pechmann (German, 1850–1902, Fig. 3.41) synthesized or discovered several new organic molecules and is remembered for Pechmann condensation and Pechmann pyrazole synthesis.

Fritz Pregl (Austrian, 1869–1930, Fig. 2.52) developed important methods for quantitative organic microanalysis that have been widely used ever since. For that work, he won the Nobel Prize in Chemistry in 1923. Professor O. Hammarsten, Chairman of the Nobel Committee for Chemistry, announced the award [https://www.nobelprize.org/prizes/chemistry/1923/ceremony-speech/]:

> The improvement consists of the fact that Pregl converted previously used methods for quantitative analysis of relatively large quantities of substances to micro-analytical methods. This has made it possible to carry out these analyses of such small quantities of substances, the analysis of which would previously have been impossible, with exactly the same accuracy, but with great savings in time, labour, and expense. [...]
>
> Pregl's micro-analysis can be equally well applied in all fields of organic chemistry. It has already proved itself in a great number of cases, and has stood the test in this country as well. It opens promising prospects for research in the future, particularly in the vast field of biochemistry. There is every reason to hope that micro-analysis will make possible fruitful study of a great number of substances which so far, in some respects at least, have been practically inaccessible to exact chemical investigation. Such substances, for instance, include enzymes, vitamins and hormones, the extremely great significance of which for the vital processes is well known.

Vladimir Prelog (Austro-Hungarian/Croatian, 1906–1998, Fig. 3.41) made many important discoveries regarding the stereochemistry of organic molecules and the shapes of enzymes, for which he won the Nobel Prize in Chemistry in 1975. Professor Arne Fredga of the Royal Academy of Sciences explained his research [https://www.nobelprize.org/prizes/chemistry/1975/ceremony-speech/]:

> Professor Prelog has worked in many fields of stereochemistry, and often the problems have been connected with the geometrical shapes of the molecules and their influence on the course of the reactions. [...]
>
> Professor Prelog has also made important contributions to enzyme chemistry. He has studied enzymatic reactions on small molecules and in particular oxidation or reduction processes. The experiments may be more or less successful depending on how the enzyme and the other molecule fit together geometrically. By systematic experiments with various small molecules of well-defined shapes, it was possible to construct a "map" of the active part of the enzyme molecule. The results have recently been confirmed in a special case by Swedish scientists using x-ray methods.
>
> Professor Prelog has also with ingenuity and penetration discussed and analysed the fundamental concepts of stereochemistry, not least the conditions for chirality in large and complicated molecules.

Prelog also built up long-lasting research programs in the Kaštel/Pliva pharmaceutical company, leading to work on antibiotics from sulfa drugs to azithromycin.

Robert Pschorr (German, 1868–1930, Fig. 3.42) worked on the synthesis of complex organic molecules and is best known for Pschorr cyclization.

Rudolf Pummerer (Austrian, 1882–1973, Fig. 3.42) focused on the chemistry of sulfoxides and free radicals, and remains known for the Pummerer rearrangement.

Sergey Reformatsky (Russian but educated in Germany, 1860–1934, Fig. 3.42) studied organic synthesis and metal catalysts, and is remembered for the Reformatsky reaction.

Karl Reichenbach (German states, 1788–1869, Fig. 3.42) discovered many useful organic molecules, including phenol and paraffin.

Walter Reppe (German, 1892–1969, Fig. 3.42) was an enormously influential figure in applied organic chemistry, both in Germany and in other countries (through postwar reports on his chemical methods). His work focused on turning Germany's large natural supply of coal into acetylene, and then converting the acetylene into a vast variety of useful chemical molecules, a process that became known as Reppe chemistry.

Karl Wilhelm Rosenmund (German, 1884–1965, Fig. 3.42) received his Ph.D. under Otto Diels. His name is associated with Rosenmund reduction and the Rosenmund-von Braun reaction.

Otto Ruff (German, 1871–1939, Fig. 3.43) conducted important work in high-temperature chemistry, the chemistry of sugars, polymers, and other areas of organic chemistry. He is best known for Ruff degradation.

Traugott Sandmeyer (Swiss, 1854–1922, Fig. 3.43) was an expert at synthesizing complex organic molecules. He is still remembered for the Sandmeyer reaction and Sandmeyer synthesis.

Rudolf Schmitt (German, 1830–1898, Fig. 3.43), along with his Ph.D. advisor Adolph Kolbe, discovered the Kolbe-Schmitt reaction. He also conducted research on salicylic acid and other areas of organic chemistry.

As illustrated in Fig. 3.44, Carl Schotten (German, 1853–1910) and Eugen Baumann (German, 1846–1896) developed Schotten-Baumann reactions (1883), which are used to synthesize a wide variety of useful organic molecules.

Hermann Staudinger (German, 1881–1965, Fig. 3.43) made an enormous number of contributions in the fields of organic chemistry, polymers, and colloids. He discovered ketene molecules and the Staudinger reaction, and won the Nobel Prize in Chemistry in 1953. Professor A. Fredga, a member of the Nobel Committee for Chemistry, praised his work [https://www.nobelprize.org/prizes/chemistry/1953/ceremony-speech/]:

> Professor Staudinger. More than thirty years ago you expressed the view that a chemical molecule can attain an almost arbitrary size and that such macromolecules are of great importance in our world. Your view was based on logical reasoning. You drew attention to the fact that what are termed high polymers are formed when for some reason or another an anticipated ring closure fails to occur. You thus submitted an argument which an organic chemist cannot ignore. Moreover, in extensive and painstaking series of studies you have provided experimental proof.

Johann Stobbe (German, 1860–1938, Fig. 3.33) is best known for developing Stobbe condensation, a step that ever since then has been widely utilized in the synthesis of organic molecules.

Adolph Strecker (German, 1822–1871), Friedrich Gustav Carl Emil Erlenmeyer, Jr. (German, 1864–1921), Fritz Arndt (German, 1885–1969), and Bernd Eistert (German, 1902–1978) developed methods to artificially synthesize amino acids, the building blocks of proteins. See Fig. 3.45.

Johannes Thiele (German, 1865–1918, Fig. 3.43) synthesized a number of novel types of organic molecules and is still known for the Thiele tube.

Bernhard Tollens (German, 1841–1918, Fig. 3.43) determined the structures of several sugar molecules and developed the Tollens reagent.

Alfred Treibs (German, 1899–1983, Fig. 3.46) founded organic geochemistry. He discovered porphyrin molecules in petroleum, proving that petroleum originated from ancient plants and animals.

Fritz Ullmann (German, 1865–1939, Fig. 3.46) worked with and married Irma Goldberg. He developed several synthetic dye molecules and is remembered for the Ullmann reaction and Ullmann condensation. He also edited the *Enzyklopädie der Technischen Chemie*, which has been updated by others since then and is still in use today.

Jacobus Hendricus van 't Hoff (Dutch, 1852–1911, Fig. 3.46) made many important discoveries in the stereochemistry of organic molecules as well as in physical chemistry. He won the Nobel Prize in Chemistry in 1901. C.T. Odhner, President of the Royal Swedish Academy of Sciences, described his research [https://www.nobelprize.org/prizes/chemistry/1901/ceremony-speech/]:

> As a result of his investigations in the fields of atomic and molecular theory van 't Hoff has made the most important discoveries in theoretical chemistry since Dalton's time.
>
> With regard to atomic theory van 't Hoff, following an idea put forward by Pasteur, advanced the hypothesis that the elementary atoms have attachment points geometrically oriented in space—a hypothesis which in so far as carbon compounds are concerned led to the theory of the asymmetry of carbon atoms and to the founding of stereochemistry.
>
> Still more revolutionary were van 't Hoff's discoveries in the field of molecular theory. van 't Hoff's investigations showed that the law, which has been named after the Italian Avogadro, according to which the number of gas molecules in a given volume is the same for all gases at the same pressure and temperature, embraces not only substances in the gaseous phase but also those in solution, provided that their pressure, known as osmotic pressure, is taken into account in the same way as the gas pressure in the case of gases. He proved that gas pressure and osmotic pressure are identical, and thereby that the molecules themselves in the gaseous phase and in solutions are also identical. As a result of this the concept of the molecule in chemistry was found to be definite and universally valid to a degree hitherto undreamed-of. He also discovered how to express the state of chemical equilibrium in reactions and the electromotive force which a reaction can produce; he explained how the transition occurs between the various modifications of the elements, between hydrates of differing water contents, how double salts are formed, etc.
>
> By applying these simple principles, which were originally borrowed from mechanics and thermodynamics, van 't Hoff became one of the founders of chemical dynamics.

Jacob Volhard (1834–1910, Fig. 3.46) and his student Hugo Erdmann discovered the Volhard-Erdmann cyclization reaction. Volhard also trained several other students who went on to make great discoveries, most notably Hermann Staudinger.

Otto Wallach (German, 1847–1931, Fig. 3.46) focused on organic molecules that are alicyclic, or both aliphatic and cyclic. His name is associated with the Wallach rearrangement, Wallach degradation, and Wallach's rule. He won the Nobel Prize in Chemistry 1910, and Professor O. Montelius, President of the Royal Swedish Academy of Sciences, praised his research [https://www.nobelprize.org/prizes/chemistry/1910/ceremony-speech/]:

> Through this pioneering work Wallach opened up a new field for research, which could be investigated further with good hope of success. And it is true that this field was immediately tackled by a great number of research scientists in various countries. Organic chemistry, during the decade that followed, was characterized by the study of the so-called alicyclic compounds, among which the terpenes and the closely related types of camphor with their derivatives played the most important part. Wallach himself, by overcoming considerable difficulties with admirable success and though perseverance, made continuous progress in the field opened up by himself. An extraordinarily large number of compounds were prepared by him and he also determined their structure. Apart from the terpenes proper, he also investigated and scientifically characterized various previously known or newly discovered natural products, such as alcohols, ketones, sesquiterpenes and polyterpenes belonging to the terpene series, which in part are also of great significance in biological and technical respects. For this reason the alicyclic series has, since the middle of the eighties, assumed such size and importance as to make it the equal of the other three main series within organic chemistry. Wallach contributed more towards this than any other research scientist.
>
> Wallach's research activity did not only decisively influence theoretic chemistry, but also chemical industry, namely that branch of the industry which processes essential oils.

Conrad Willgerodt (German, 1841–1930, Fig. 3.46) studied the chemistry of ketones, discovered iodosobenzene, and is still remembered for the Willgerodt reaction.

Johannes Wislicenus (German, 1835–1902, Fig. 3.47) made a number of important discoveries regarding the stereochemistry of organic molecules.

Georg Wittig (German, 1897–1987, Fig. 3.47) is famous for the Wittig reaction and the Wittig rearrangement. He developed a new method to produce alkenes, or hydrocarbon molecules containing double bonds, for which he won the Nobel Prize in Chemistry in 1979. Professor Bengt Lindberg of the Royal Academy of Sciences explained the importance of Wittig's work [https://www.nobelprize.org/prizes/chemistry/1979/ceremony-speech/]:

> Georg Wittig has provided many significant contributions in organic chemistry. The most important of these is the discovery of the synthetic method which bears his name, the Wittig reaction. In this, phosphorus ylides, a type of compound which he discovered, are allowed to react with carbonyl compounds. An exchange of groups takes place and the result is a compound in which two carbon atoms have been joined by a double bond. Since many natural products with biological activity contain such bonds, this elegant

> method has found wide-spread use, for example in the industrial synthesis of vitamin A.

Alfred Wohl (German, 1863–1933, Fig. 3.47) worked in sugar chemistry, developed novel catalysts, and is remembered for Wohl degradation, the Wohl-Aue reaction, and the Wohl-Ziegler reaction.

Ludwig Wolff (German, 1857–1919, Fig. 3.47) received his Ph.D. under Rudolph Fittig and conducted important research in organic chemistry; his name is now associated with the Wolff rearrangement and the Wolff reduction.

Charles Adolphe Wurtz (Franco-German, studied in Germany, 1817–1884, Fig. 3.47) discovered the aldol reaction, what is now called the Wurtz reaction, ethylamine, and ethylene glycol.

Ernst Carl Theodor Zincke (German, 1843–1928, Fig. 3.47) received his Ph.D. under Friedrich Wöhler, and in turn was the doctoral advisor of Otto Hahn. He made many organic chemistry discoveries for which he is remembered, such as Zincke reaction, Zincke nitration, Zincke-Suhl reaction, etc.

3.2.3 Organometallic Chemistry

German-speaking scientists made many important contributions to organometallic chemistry, the study of carbon-rich organic molecules bound to metal atoms.[4] Organometallic compounds are especially useful in catalyzing reactions for the large-scale production of many industrial chemical products. Knowledge about them is also useful for understanding the natural catalytic properties of many enzymes.

Ludwig Mond (German, 1839–1909, Fig. 3.48) founded the field of organometallic chemistry and was one of the pioneers of industrial chemistry. He discovered metal carbonyls such as nickel tetracarbonyl (1890) and used his discovery to make a fortune purifying nickel in the United Kingdom. He also ran an industrial research program that made several other important chemical discoveries. Oxford University's *Biographical Dictionary of Scientists* summarized some of his research history [Porter 1994, pp. 492–493]:

> He studied chemistry at Marburg (under Adolf Wilhelm Hermann Kolbe) and Heidelberg (under Robert Bunsen) [...]
>
> In 1879, Mond became interested in the production of ammonia, an intermediate in the Solvay process which was increasingly being used as an artificial fertilizer. One outcome was the development of the Mond producer gas process, in which carbon monoxide and hydrogen are produced by alternately passing air and steam over heated coal or coke (and the hydrogen used to convert nitrogen into ammonia). [...] An interesting extension of this work was the attempt, with the assistance of K. Langer, to turn the energy of the fuel directly into electrical energy. This early fuel cell, which used porous plates moistened with sulphuric acid, was not developed further at that time. [...]
>
> One unexpected result of the producer gas process came from Mond's observation that nickel is corroded by gases containing carbon monoxide. This led, in 1889, to the discovery of nickel carbonyl, $Ni(CO)_4$, one of the first organometallic compounds. After two years' work, with Langer and Quincke, he had developed a new extraction process for nickel.

Johann (John) Ulric Nef (Swiss, 1862–1915, Fig. 3.48) received his Ph.D. under Adolf von Baeyer at the University of Munich, then spent his career in the United States. He studied carbene molecules, discovered Nef synthesis and the Nef reaction, and applied those methods to organic compounds containing metal ions. The American Council of Learned Societies summarized some of his other contributions to organic chemistry [ACLS 2000, pp. 636–637]:

> A great experimentalist and pioneer in theoretical organic chemistry, whose theoretical work clearly contains the germs of the present concepts of free radicals, transition states, and polymerization. Topics studied included the apparently bivalent carbon compounds and their dissociation, and the action of alkali and alkaline oxidizing agents on the sugars.

Wilhelm Schlenk (German, 1879–1943, Fig. 3.48) discovered organolithium compounds and studied organomagnesium compounds. He remains known for the Schlenk equilibrum, the Schlenk flask, and the Schlenk line.

Franz Hein (German, 1892–1976, Fig. 3.48) focused on organometallic chemistry for his whole career, studying organic compounds containing bismuth, chromium, magnesium, and other metal ions. *ABC Geschichte der Chemie* succinctly listed some of Hein's scientific accomplishments [Engels et al. 1989, p. 204]:

> Umfangreiche Arbeiten auf dem Gebiet der Organometall-Komplexchemie. Entdeckung einer Klasse chromiumorg. Verbindungen (1919); Arbeiten über Metallalkyle (darunter Quecksilberalkyle), Chromium(III)-dihalogen-alkoholate, Organometall-Eisentetracarbonyle, Komplexe des Chromiums mit 2,2'-Dipyridyl; Chromiumphenylverbindungen; Maskierung von Metallionen durch Komplexbildung; Bestimmungsmethode für Wasserstoff mittels $AgMnO_4$.

> Extensive work in the field of organometallic complex chemistry. Discovery of a class of chromium-organic compounds (1919); work on metal alkyls (including mercury alkyls), chromium(III) dihaloalcohols, organometallic iron tetracarbonyls, complexes of chromium with 2,2'-dipyridyl; chromium phenyl compounds; masking of metal ions by complexation; determination method for hydrogen using $AgMnO_4$.

Walter Otto Hieber (German, 1895–1976, Fig. 3.48) made a variety of important discoveries in organometallic chemistry, including organic molecules containing iron, manganese, osmium, rhenium, and other metals. His name remains attached to the Hieber base reaction. He was the doctoral adviser of Ernst Otto Fischer and Erwin Weiss (see below).

Karl Ziegler (German, 1898–1973, Fig. 3.49) won the Nobel Prize in Chemistry in 1963 for his work on organometallic chemistry and its application to polymer production. Professor A. Fredga of the Nobel Committee for Chemistry praised Ziegler's innovations in that area [https://www.nobelprize.org/prizes/chemistry/1963/ceremony-speech/]:

> Professor Ziegler has found entirely new methods of polymerization. Studying organometallic compounds, he discovered that organoaluminium compounds, which are easy to prepare, are particularly suitable for work on the industrial scale. Peculiar electrical forces operate around an aluminium-carbon bond in a hydrocarbon chain: reactive molecules are drawn in and sandwiched between the carbon atom and the aluminium atom, thus increasing the length of the chain. All this happens much more quietly than in free-radical reactions. When the chain is long enough, we detach the aluminium and thus stop the further growth of the molecule. The combination of aluminium compounds with other metallic compounds gives Ziegler catalysts. These can be used to control polymerizations and to obtain molecular chains of the required length. However, many systematic experiments—and indeed some accidental findings—were necessary to reach this stage. Ziegler catalysts, now widely used, have simplified and rationalized polymerization processes, and have given us new and better synthetic materials.

Similarly, Ernst Otto Fischer (German, 1918–2007, Fig. 3.49) won the Nobel Prize in Chemistry in 1973 for his research on organometallic chemistry (along with Geoffrey Wilkinson). Fischer studied ferrocene, created cobaltocene in 1953, and synthesized bis(benzene) chromium together with his student Walter Hafner in 1955. Professor Ingvar Lindqvist of the Royal Academy of Sciences explained Fischer's discoveries [https://www.nobelprize.org/prizes/chemistry/1973/ceremony-speech/]:

> It seems to be appropriate to put forward these views when speaking of this year's Nobel laureates in chemistry, professors Fischer and Wilkinson. The facts were available for all the chemists of the world to see, but the right interpretation was lacking. Once the correct hypothesis was arrived at by fantasy or intuition, it readily lent itself to simple processes of logical deduction. I am of course referring to the way in which they together with the former Nobel laureate Woodward reached the conclusion that certain compounds could not be understood without the introduction of a new concept, namely that of the sandwich compound. This expression applies to the structure of these compounds, which can be thought of as a metal atom—the filling—sandwiched between two flat molecules. Now the science of chemistry involves, of course, more than flashes of visionary inspiration, and both Fischer and Wilkinson did not hesitate to confirm and develop the concept of the sandwich compound by an intensive experimental effort. This they did by the successful synthesis of a large number of compounds which were analogous to the initially discovered ferrocene (named by Woodward in analogy with benzene), but with other metals than iron, and with other flat molecules than the cyclopentadienyl group found in ferrocene. Amongst other things, Fischer managed to surprise chemists by preparing a sandwich of chromium between two benzene molecules. The culinary exploits were pursued further with the progress to open sandwiches, having a flat molecule on one side of the metal atom, and with only small molecules such as carbonyl, methyl or ethyl groups on the other side. [...]
>
> It is a fact that every discovery within the realm of fundamental chemical research has potential applications. The very circumstance of the stability of sandwich compounds has led to involved theoretical discussions, which have also played their part in important advances in theoretical and applied research on catalysis.

Walter Hafner (German, 1927–2004, Fig. 3.49) received his Ph.D. under Ernst Otto Fischer. He and Fischer synthesized bis(benzene) chromium in 1955. Later Hafner harnessed palladium as a catalyst in organometallic reactions for industrial chemical production.

Erwin Weiss (German, 1926–2019, Fig. 3.49) did his Ph.D. studies under Walter Hieber and analyzed the structure of bis(benzene) chromium soon after it was synthesized by Ernst Otto Fischer and Walter Hafner. He spent the rest of his career investigating organic molecules containing lithium, sodium, potassium, rubidium, caesium, magnesium, copper, and other metal ions.

3.2.4 Synthetic Fuels

The German-speaking world had large deposits of coal but little oil, natural gas, or most other natural resources. Therefore, especially when imported resources were embargoed or too expensive, there was a strong incentive to harness organic chemistry to convert coal into synthetic liquid fuels, synthetic gaseous fuels, synthetic motor oil, and a variety of other synthetic hydrocarbon products.[5]

In 1913, Friedrich Bergius (German, 1884–1949) created and Carl Bosch (German, 1874–1940) scaled up the Bergius high-pressure process for producing synthetic liquid fuels from coal, for which they both won the Nobel Prize in Chemistry 1931. See Fig. 3.50. Professor W. Palmær, Member of the Nobel Committee for Chemistry, announced the award [https://www.nobelprize.org/prizes/chemistry/1931/ceremony-speech/]:

> You, Professor Bosch, were the first to enrich the chemical industry with this powerful tool, for the production of ammonia from the elements. Between the presentation of the scientific bases of this synthesis and its industrial exploitation lay a mighty chasm, which you bridged, inter alia, by the brilliant invention and construction of the high-pressure apparatus. By doing so, you made it possible for nitrogen to be made available to mankind in inexhaustible quantities, in a form suitable for agriculture, and even at lower prices than hitherto. Furthermore, you developed high-pressure methods for the production of other important substances. By virtue of this, the Academy wishes to thank you and congratulate you, and requests you to receive the distinction from the hands of His Majesty the King.
>
> General Director Bergius. You undertook to tackle a problem which, in its importance for humanity, can be compared with the solution of the nitrogen question. You have shown how, by the injection of hydrogen under pressure, pit coal, brown coal, and other carbon-bearing materials can be processed to liquid fuels which are considered indispensable in modern life for the propulsion of ships and vehicles. You have thereby obviated the danger which threatened of exhaustion of petroleum deposits, an event which must have happened sooner or later. In your work, you arrived at the high-pressure method quite independently. On the basis of your work, a powerful industry has already been formed.

Similarly, in 1925, Franz Fischer (German, 1877–1947) and Hans Tropsch (Austrian, 1889–1935) created the Fischer-Tropsch process for synthesizing fuels and other hydrocarbons, as shown in Fig. 3.51. The chemist and chemical historian Aaron Ihde explained [Ihde 1984, p. 683]:

> Perhaps of even greater interest in this connection is the Fischer-Tropsch process developed in the twenties by the Germans Franz Fischer (1877–1947) and Hans Tropsch (1889–1935). Water gas [$CO + H_2$] passed over suitable metal oxide catalysts at about 200^o C. and moderate pressure is converted into hydrocarbons suitable for motor fuels. The process was ready for commercial production of hydrocarbons after 1935 and was an important factor in the German war effort, as evidenced by the attention given to synthetic oil plants by Allied bombers. The hydrocarbons thus produced also were oxidized to fatty acids to help Germany overcome a shortage of food fats.

At the end of World War II, Allied countries seized all information on German synthetic fuel production processes. Due to limited worldwide resources and concerns about global warming and pollution, such synthetic fuels or related approaches may have a renewed importance in the future.

3.2.5 Liquid Crystals

Scientists from the German-speaking world discovered and developed liquid crystals, which can respond to changing temperatures, voltages, pressure, or other conditions by changing their optical properties.[6] One simple application of liquid crystals is to create materials that change colors over a custom-designed range of temperatures. More importantly, electrically controlled liquid crystals are now widely used in electronic display panels from watches to television screens (Fig. 3.52).

Friedrich Reinitzer (Austrian, 1857–1927), a biochemist, discovered liquid crystals in 1888. He noticed the liquid crystal properties of cholesteryl benzoate that he had purified from plants, and he continued to study those properties for several years.

After first discovering liquid crystals, in 1888 Reinitzer enlisted the assistance of Otto Lehmann (German, 1855–1922) in further analyzing and experimenting with them. Lehmann was a physicist and already an expert on the optical properties of materials that could rotate the polarization of light or bend light differently depending on its direction of polarization. Lehmann spent the rest of his life studying the optical properties of liquid crystals in conjunction with polarizers, the temperature-sensitive phase transitions of liquid crystals, and the microscopic and chemical properties of liquid crystals. He was the one who named them "liquid crystals," and he produced a string of publications that firmly established this field, explored its applications, and promoted it to other scientists. For all of his research on liquid crystals, Lehmann was repeatedly nominated for a Nobel Prize, but unfortunately he never won.

Inspired by the pioneering work of Reinitzer and Lehmann, Daniel Vorländer (German, 1867–1941) spent his career synthesizing and analyzing hundreds of different liquid crystal compounds. He also trained a number of students in this field.

Based on the decades of work by Reinitzer, Lehmann, Vorländer, and other scientists that they inspired and/or trained,[7] by the end of World War II, there was a large body of research on the synthesis, properties, and applications of liquid crystals. After the war, all of that information and many of the relevant researchers were seized and harnessed by Allied countries. For example, liquid crystals and some of their applications were described in BIOS 1688, *Radiological Activities in Germany*, p. 12:

> 6. Thermo-Colour Methods
> Berthold attempted to apply Thermo-Colour materials, developed by Dr. Penzig of I.G. Farben in 1939, to non-destructive methods of testing. With these materials it is possible to detect small changes of temperature of the order of a few degrees in temperature ranges up to 360^{o}C. It was Berthold's intention to apply the method to inspect the fit or surface contact of cast inserts, duplex bearings, etc.

As a result of that technology transfer, in the decades after World War II, liquid crystals slowly began appearing in commercial products in Allied countries—first novelty mood rings, then small liquid crystal displays for watches and calculators, and finally larger liquid crystal displays for everything from smart phones to computers to wall-sized television screens. Much more archival research should be conducted to elucidate the full history of liquid crystal research in the German-speaking world, as well as the transfer and influence of that research in other countries.

3.2.6 Technology Transfer out of the German-Speaking World

Many chemical innovations were transferred from the German-speaking world to other countries before World War II, in the form of published papers and patents, commercial transactions, foreign students who visited the German-speaking world, German and Austrian assets seized by other countries during World War I, and chemists who left the German-speaking world to seek careers elsewhere and/or to flee the rising tide of antisemitism and National Socialism.

All remaining chemical innovations, of which there were still a huge number, were seized by Allied countries at the end of World War II. For some examples, see pp. 421–423, as well as the large number of chemistry-related BIOS ER, BIOS, BIOS Misc., BIOS Overall, CIOS ER, CIOS, FIAT, *FIAT Review*, JIOA, NavTecMisEu LR, and NavTecMisEu reports in the Bibliography.

In September 1945, R. P. Linstead and T. J. Betts, the British and American chairs of the Combined Intelligence Objectives Subcommittee (CIOS), gave a very incomplete yet still highly impressive list of important German innovations in synthetic chemistry that had been found by U.S. and U.K. investigators [AFHRA A5186 electronic version pp. 904–1026, Ch. 4, pp. 54–56]:

> The German war time economy was based on its abundant supplies of coal and therefore coke; water gas; on calcium carbide from coke and lime, leading to acetylene; on nitrogen and hydrogen, leading to ammonia; and on salt, leading to chlorine and caustic soda. From these basic products the entire German chemical industry was erected by the following catalytic processes:
>
> 1. Hydrogenation of coal, tar, and oils, and their subsequent conversion into motor fuels, and diesel oils with its long line of by-products such as lubricants, lower aliphatic hydrocarbons and olefines and compounds containing oxygen, like phenol and its homologues.
> 2. The variety of processes of catalytic conversion of CO and H_2 in different proportions leading to methanol, ethanol and their homologues up to long chain fatty alcohols.
>   (a) The synthesis of isobutanol and its conversion to isobutylene and isooctane.
>   (b) The production of hydrocarbons according to the Fischer-Tropsch synthesis leading to aliphatics and olefines from low to very high chain length. Further conversion of the olefines so obtained by addition of CO and H_2 of the type of the oxo reactions or with CO and water according to the fatty acid synthesis of Reppe.
> 3. The reactions of acetylene and ethylene and their many derivatives leading to solvents, plastics, rubber and synthetic fibres.
> 4. The latest types of aliphatic reactions of acetylene and olefine with CO.
>
> Of particular significance is the manufacture of synthetic rubber (BUNA) by the Reppe process, which uses only 1/3 of the quantity of carbide and acetylene required in the conventional process. The discovery of the "Koresine" tacking process is regarded as being of primary importance. The application of this process to the synthetic rubber industry in the U.S. resulted in increased production, and did much to eliminate the threat of a cut in tire production during the critical phase of combat operations.

> The development of plastics covered a very large number of polymer products, among which the polyisocyanates and polyurethanes (Demodurs), the superpolyamides of the Igamid and Perlon types (German nylon) consisting of dibasic acids, diamides, the polyethylenes (Lupolenes), the vinylchloride polymers (Igelites), the vinylacetate polymers (Nowiliths), as well as their derivatives, represent outstanding achievements.

Similarly, Linstead and Betts listed a number of important German innovations for synthetic fuels and oils that had been found by U.S. and U.K. investigators [AFHRA A5186 electronic version pp. 904–1026, Ch. 4, pp. 59–60]:

> The two principal features of the German synthetic fuels and lubricants industry consisted of the hydrogenation of coal, coal tar, and coal tar products; and the Fischer-Tropsch process for the production of fuel from water gas.
>
> The acquisition of a vast amount of specific German data has been one of the significant accomplishments resulting from exploitation of intelligence in this field. Should the U.S. or Great Britain be faced with another national emergency, adequate supplies of fuels and lubricants will be much more assured as the result of this information.
>
> The DHD process for obtaining aviation fuels by hydrogenation and conversion to aromatics is a development hitherto unknown in this detail.
>
> The Germans were discovered to have adopted new methods which permitted the successful hydrogenation of brown coal from Rhineland reserves. They had also perfected a novel process for producing water gas from brown coal.
>
> Interrogation of German authorities and examination of documents and plants revealed that the Fischer-Tropsch process could not be expected to yield more than 15 to 20% of fuel and oil requirements of the German economy. However, the Fischer-Tropsch process has a certain advantage of yielding crude chemicals which possess a considerable potential for further refining.
>
> The Germans have recently developed a new iron catalyst which could be used to supplant catalysts of conventional cobalt type.
>
> The following additional discoveries resulting from investigation of the German fuel and oil industry are worthy of mention:
>
> 1. New high grade aviation lubricants obtained by polymerization of ethylene.
> 2. New methods of testing fuels and lubricants.
> 3. Fairly complete specifications for German fuels and lubricating oils.
> 4. Details of German shale oil distillations and the refining of these distillates.
>
> Many laboratory improvements were encountered which had not been applied to industrial use, but which will prove of value in U.S. and British development work.

The organic chemistry methods, discoveries, and expertise that were transferred out of the German-speaking world created our modern world of consumer products from colored fabrics and plastic materials to pharmaceuticals and liquid crystal display screens.

3.3 Chemistry of Foods and Drinks

In food and drink production, as in many other areas, the German-speaking world possessed very limited natural resources. When key food and drink ingredients from foreign sources became too expensive during peacetime, and especially when key ingredients were embargoed and unavailable during World Wars I and II, German-speaking scientists developed a number of highly innovative food substitutes and related synthetic products and preservatives. This is a large field, and only a few examples are briefly discussed in this section, including:

3.3.1. Synthetic flavors

3.3.2. Synthetic drinks

3.3.3. Synthetic fats

3.3.4. Synthetic protein products

3.3.5. Preservatives

Several of the above innovations, those related to biotechnology, are covered in more detail in Appendix A.

Even after the wars, several of these innovative food and drink products continued to be used both in German-speaking countries and in other countries around the world that adopted the innovations, especially in cases where the innovative product was cheaper or better than the original food, drink, or ingredient. The strong interest by other countries in these innovations is demonstrated by the large number of BIOS, CIOS, and FIAT reports that Allied countries wrote about them.

3.3.1 Synthetic Flavors

Karl Reimer (German, 1845–1883), Wilhelm Haarmann (German, 1847–1931), and Ferdinand Tiemann (German, 1848–1899) found the molecular structure of natural vanillin flavor from vanilla beans, and developed purely chemical methods of synthesizing it in 1874, as illustrated in Fig. 3.53. In the modern world, most vanillin flavor is chemically synthesized using these same or similar methods, since chemical synthesis is less expensive than growing and processing vanilla beans.

In 1879, Constantin Fahlberg (Russian but studied and worked in Germany, 1850–1910) discovered the artificial sweetener saccharin. By the 1880s, saccharin was synthesized on a large scale in Germany (Fig. 3.54), and it has been sold around the world ever since [BIOS 1576].

During World War I, Hermann Staudinger (German, 1881–1965) and Paul Immerwahr (German, 1886–1926) developed an artificial substitute for scarce black pepper: ground nutshells soaked in chemically synthesized piperine or piperine derivatives (the key ingredient of real black pepper) [Vaupel 2010, 2011]. See Fig. 3.55.

By World War II, the German-speaking world had developed a number of other artificial spices, such as synthetic allspice, cinnamon, cloves, cardamom, and nutmeg [Vaupel 2011; CIOS XXXII-47; FIAT 244].

Prof. Dr. H. STAUDINGER, Zürich (Schweiz).

Verfahren zur Herstellung eines Ersatzmittels für scharf schmeckende Stoffe.

In der Literatur wird im allgemeinen angenommen, daß der scharfe Geschmack des Pfeffers auf das in ihm enthaltene Piperin zurückzuführen sei. Versuche, welche zur Herstellung von Stoffen unternommen wurden, die an Stelle von Pfeffer, Paprika und andern scharf schmeckenden Produkten verwendet werden können, haben dies bestätigt. In der Literatur ist ferner bekannt, daß einige dem Piperin nahstehende Stoffe scharf schmecken (Scholz, B. 28, Seite 1187). Diese Körper sind aber, wie das Piperin selbst, schwer zugängliche Substanzen, und es wurde deshalb früher nie der Versuch gemacht, durch Vermischen dieser synthetischen Substanzen mit andern Materialien scharf schmeckende Stoffe technisch herzustellen, die den natürlichen Pfeffer oder andere scharf schmeckende Stoffe ersetzen können.

Eine größere Reihe von Untersuchungen hat nun das auffallende Ergebnis geliefert, daß zahlreiche einfach gebaute, leicht herstellbare Stoffe dieselben, ja noch bessere physiologische Eigenschaften haben, wie das Piperin selbst. Es sind dies säureamidartige Verbindungen von hydrierten Pyridinen, hauptsächlich Piperidin und seinen Homologen mit aliphatisch-aromatischen Carbonsäuren, wie Zimtsäure, Phenylisocrotonsäure, Zinnamenylacrylsäure, deren Hydrierungsprodukten und Substitutionsprodukten. Auffallenderweise ist nämlich für das Zustandekommen der physiologischen Eigenschaften des Piperins die Dioxymethylengruppe von keiner Bedeutung und ebenso können auch die Doppelbindungen in der zweifach ungesättigten Säure ganz oder teilweise aufgehoben werden, ohne daß die physiologischen Eigenschaften verändert werden. Die genannten synthetischen Piperine, die für sich allein viel zu scharf schmecken, um als Genußmittel in Betracht zu kommen, werden nun gemäß dem vorliegenden Verfahren dadurch zur Herstellung synthetischer Genußmittel verwandt, daß sie in geeigneter Weise mit Verdünnungsmitteln vermischt werden. Es können sowohl feste wie flüssige Verdünnungsmittel in Betracht kommen. Nach Zusatz von festen Verdünnungsmitteln in Form von Pulvern entstehen Produkte, die an Stelle des Pfeffers in den Handel gebracht werden können.

3.3.2 Synthetic Drinks

During wartime, caffeine was an important stimulant, yet its natural sources—tea leaves and coffee beans—were difficult to obtain due to embargoes. Therefore, many German-speaking chemists developed artificial methods of producing caffeine (Fig. 3.56). Most of those methods involved direct chemical synthesis of caffeine by a long series of reactions [BIOS 306; BIOS 449; BIOS 1404; CIOS XXVI-9; FIAT 71; FIAT 885]. However, some especially ingenious (or desperate) scientists also developed and demonstrated methods to farm large quantities of snake urine, which contains an especially high concentration of uric acid, and then convert that uric acid to caffeine [BIOS 449; see p. 2354].

Amalie Melitta Bentz (German, 1873–1950) invented paper coffee filters and the corresponding brewing system in 1908 (Fig. 3.57). She founded the Melitta coffee company.

In the 1930s, Hermann Staudinger (German, 1881–1965), Tadeusz Reichstein (Polish, educated and worked in Switzerland, 1897–1996), Max Kerschbaum (German?, 18??–10??), Eligius Freudl (Austrian, 1875–1951), and other chemists developed Coffarom and other instant coffee mixes derived from synthetic ingredients [Priesner 2014, 2016; FIAT 244; FIAT 407]. See Fig. 3.58.

In parallel during the 1930s, Max Rudolf Morgenthaler (Swiss, 1901–1980) and other chemists developed Nescafé, an instant coffee mix derived from coffee bean extracts and other natural ingredients [Priesner 2014, 2016]. See Fig. 3.59.

During World War II, German-speaking scientists also made a number of improvements to the processing and sterilization of fruit juices that were adopted by other countries after the war [e.g., Kertesz 1946; FIAT 50].

3.3.3 Synthetic Fats

In the 1930s and early 1940s, many German-speaking scientists developed artificial methods to produce lipids or fats for foods, soaps, fuels, and other products.

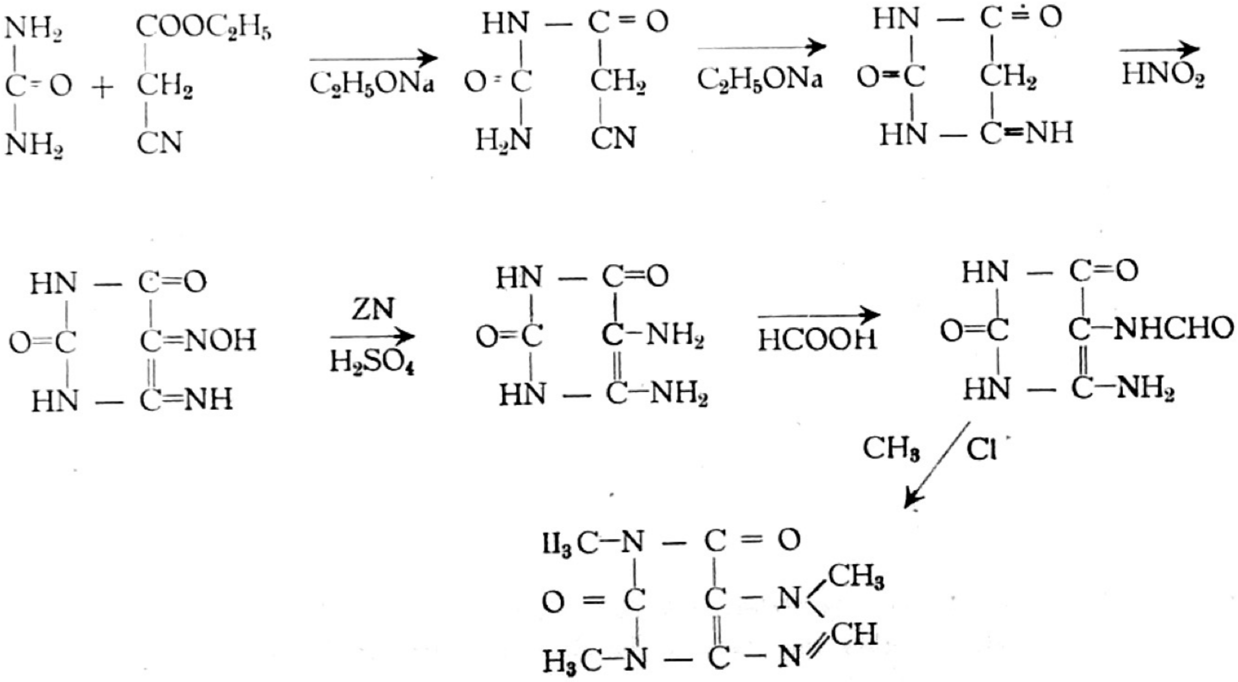
Glycerin, sterols, fatty acids, and triglycerides were produced from chemical synthesis on an industrial scale and sold for food products and other applications [BIOS 86; BIOS 805; FIAT 213; FIAT 407]. See Fig. 3.60.

Fats were produced and purified from various strains of cultured algae and fungi using biotechnology methods [BIOS 236; BIOS 691; FIAT 371]. In addition to the food applications, this appears to have been the origin of algal and other microbial biofuel technologies. See Fig. 3.61.

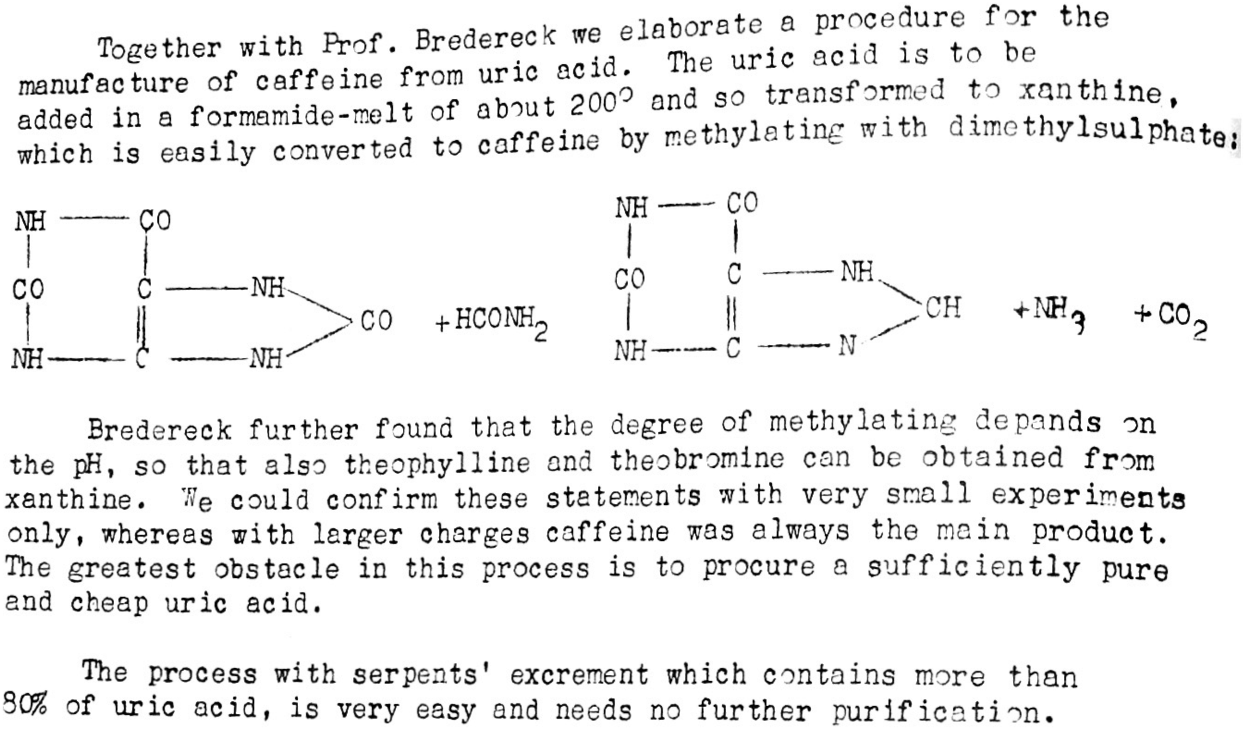
Artificially produced fats were used to make a variety of food products, including cooking oil, cooking fat (shortening), margarine, creamer, salad oil, chocolate [Clarke 1946], synthetic human milk (infant formula) [FIAT 107], etc. [See also Gemmill 1946 for examples of other innovations in butter production.]

Artificial caffeine

From chemical synthesis [FIAT 885]



From conversion of uric acid from snake urine [BIOS 449]



Together with Prof. Bredereck we elaborate a procedure for the manufacture of caffeine from uric acid. The uric acid is to be added in a formamide-melt of about 200° and so transformed to xanthine, which is easily converted to caffeine by methylating with dimethylsulphate:

$+HCONH_2$
$+NH_3$
$+CO_2$

Bredereck further found that the degree of methylating depands on the pH, so that also theophylline and theobromine can be obtained from xanthine. We could confirm these statements with very small experiments only, whereas with larger charges caffeine was always the main product. The greatest obstacle in this process is to procure a sufficiently pure and cheap uric acid.

The process with serpents' excrement which contains more than 80% of uric acid, is very easy and needs no further purification.

Figure 3.56: German-speaking chemists developed artificial methods of producing caffeine, including from direct chemical synthesis [FIAT 885] and from the conversion of uric acid harvested from snake urine [BIOS 449].

HERMANN STAUDINGER, OF FREIBURG, GERMANY, AND THADEUS REICHSTEIN, OF ZURICH, SWITZERLAND, ASSIGNORS TO THE FIRM INTERNATIONALE NAHRUNGS- UND GENUSSMITTEL AKTIENGESELLSCHAFT, OF SCHAFFHAUSEN, GERMANY.

METHOD OF PRODUCING ARTIFICIAL COFFEE AROMA.

No Drawing. Application filed October 15, 1926, Serial No. 141,873, and in Germany November 4, 1925.

The subject matter of the present invention is a method of artificially producing the aroma of coffee by mixing substances known to be contained in the ethereal oil of roasted coffee or substances similar in action, either artificially produced or extracted from natural products, and also the application of the obtained products to impart the aroma of roasted coffee to other substances.

In spite of numerous and costly experiments the substances which are of importance for the production of the aroma are not definitely known. Up to the present the following substances have been determined in the aroma, i. e. in the so-called coffee oil and in the roasted products respectively: pyridine, furfur-alcohol, furfurol, maltol, acetone, acetic acid, valeric acid, which has been taken for methyl-ethyl-acetic acid, further quinol and phenols having the odour of creosote, i. e. substances which singly or in mixture produe no coffee aroma.

E. Erdmann considered a colourless oil containing nitrogen with a boiling point of 93° at 13 millimetres pressure to be the characteristic odoriferous substance of the aroma, whilst Bernheimer believed derivates of phenol, the so-called caffeol, to be the bearer of the odour. The presence of the following substances was assumed: pyrrol, furfurane, trimethyl-amine and methyl-amine, formic acid and resorcinol.

A novel method of isolating the aromatic principle contained in roasted coffee has been invented, see patent application Ser. No. 80,351, filed Jan. 9, 1926, and according to which large quantities of the aroma have been produced and analyzed. The result of this was that coffee oil consists of a mixture of a great many different substances; the most important substances have been isolated and identified and the desired knowledge of the composition of the aroma has thus been gained. The following compounds have been ascertained in the aroma: hydrogen sulphide, methyl-mercaptan, furfuryl-mercaptan and higher mercaptans, dimethyl-sulphide and higher sulphides, acetaldehyde, methylethyl-acetaldehyde, furfurol, methyl-furfurol, acetone, higher aliphatic aldehydes and ketones, ketones of the furane series, diacetyl- and acetyl-propionyl, oxy-sulphides and mercaptales of carbonyl compounds with the above mentioned mercaptans, methylalcohol, higher aliphatic alcohols, acetol, furfuryl-alcohol, acetic acid, isovaleric acid and higher fatty acids, palmitic acid, esters of the former two acids with the mentioned alcohols, phenol, catechol, guaiacol, vinylguaiacol, 2,3-dioxyacetophenone, further phenols and phenol ethers of a higher valence, maltol, pyridine, pyracine, methyl-pyracine, 2,5 and 2,6 dimethyl-pyracine, higher homologues of pyracine, N-methyl-pyrrole, N-furfuryl-pyrrole, further higher pyrroles and derivates of furane and finally naphthalene.

These substances are to be found in the aroma of coffee in varying proportions and this explains the well known fact that the aroma of coffee widely varies in accordance with the kind of coffee and the method of roasting. A synthetic aroma may be produced by mixing together all the above mentioned substances, which may be obtained synthetically from other substances or from natural products; analogues and homologues may also be used.

The further research showed that some of the substances are of special importance for producing the aroma and in opposition to the old hypothesis these substances are not the phenols nor nitrogen compounds but fugitive sulphurous compounds of the mercaptan series of the general formula ASH or derivatives thereof, particularly oxy-sulphides of the formula

$$\mathrm{R{-}CH}\left\langle\begin{matrix}\mathrm{OH}\\ \mathrm{SA}\end{matrix}\right.$$

which may be obtained from carbonyl compounds, aldehydes, ketones and diketones with the above mentioned mercaptans.

It is to be observed that like or similar effects as those produced by the sulphur compounds found in the aroma of coffee may be obtained by synthetically manufactured products which are of a similar structure although not present in the natural aroma, for instance the particularly important furfuryl-mercaptan may be replaced by thienyl-mercaptan or benzyl-mercaptan; disulphides also show a similar effect.

The aroma is produced by an addition of the above mentioned sulphur-compounds, either singly or in mixture, to the other oxygen containing and nitrogen containing

UNITED STATES PATENT OFFICE

2,161,511

PRODUCTION OF SURROGATES AND ADDITIONS FOR COFFEE

Eligius Freudl, Tetschen, Czechoslovakia, assignor to Coffarom Aktiengesellschaft, Glarus, Switzerland

No Drawing. Application January 12, 1938, Serial No. 184,697. In Czechoslovakia January 23, 1937

8 Claims. (Cl. 99—74)

This invention relates to the production of surrogates and additions for coffee.

For producing surrogates and additions for coffee, it has already been proposed to employ as suitable raw materials, for example, roots or parts of the root of various genera of plants, such as bulbs of topinamber and dahlia, roots of chicory and viper's grass. These distinguish from most other raw materials by their percentage of inulin and substances similar to inulin, and, in some cases, have a peculiar characteristic bitter taste, even after having been worked into surrogates or additions for coffee, in a usual manner. This characteristic taste is undesirable, as it is a drawback to efforts to promote the more general use of the surrogates or additions for coffee produced from the above-mentioned raw materials.

The operation of working the raw materials concerned into surrogates and additions for coffee by means of the conventional drying and roasting processes results in an extensive pyrogenetic decomposition of the constituents contained in the bulbs and roots by influence of heat, whilst considerable amounts of pigments, assamar and various stimulants are formed, whereas valuable constituents tending to increase the stimulative effect go to waste by being either decomposed or rendered insoluble.

The object of the present invention is to provide an improved working process by means of which the characteristic bitter taste of the raw materials used, which hitherto penetrated through the product of roasting, can be reduced to any desired extent, completely eliminated, or even changed to a sweetish taste depending upon the manner in which the method is carried out, whereby a product of a highly stimulative effect is obtained which has an appreciable coloring capacity and an agreeable flavor.

In the process according to this invention the inulin and substances similar to inulin, as contained in the raw materials used, are hydrolysed on an industrial scale and the products of the hydrolysis, particularly the levulose, are utilized for producing melanoidin, that is, caramel, and thus for producing pigments from albumin decomposition products and sugars.

In the process according to this invention, the inulin and substances similar to inulin are hydrolysed by subjecting the raw materials to heat treatment in moist condition and their moisture content is maintained. During this heat treatment in moist condition the changing of the characteristic taste as alluded to above, that is, the removal of the bitter taste from the surrogate or addition materials for coffee, previously referred to, takes place. At the same time a relatively great amount of pigment material is already produced below the roasting temperatures since, owing to the presence of a plenteous quantity of levulose, thus of a sugar having a free carbonyl-group, the most favorable conditions for the formation of melanoidin and thus for the formation of caramel are given.

The formation of pigment material takes place at temperatures substantially lower than are usually resuired for the roasting process. The formation of pigment sets in at temperatures of about 100° C., whereas, as is well known, in the usual roasting process vigorous reaction sets in only at temperatures above 160° C., so that the undesirable transformations, which are a direct consequence of the elevated roasting temperatures, are avoided and, apart from this, the yield is increased.

The removal of the bitter taste as obtained, for example, for chicory may be due to the fact that the bitter substances of glucoside-like nature which oftentimes go with the inulin are partially destroyed by the heat treatment in moist condition or their effect is decreased, so that the product finally obtained is refined by the taste of the bitter substances being improved.

The intensity of the heat treatment in moist condition, if required, can be so increased, by conjoint action of pressure, that the inulin is sufficiently decomposed, that is, the decomposition is continued until the inulin is at least partly transformed into levulose, by which means separate roasting of the material may under certain circumstances be dispensed with.

These features distinguish the process according to the invention from known processes in which inulin-containing raw materials suitable for the production of surrogates and additions for coffee are steamed for removing the bitter substances prior to the roasting and are then extracted by means of boiling water, and also distinguish from known processes in which roasted granular inulin-containing raw materials, for the purpose of being powdered with chicory dust, are made sticky by means of steam or water, in order to provide the necessary adhesion for the powder to remain in place, particularly, while the material is subsequently dried, and finally roasted.

The application of the process according to the invention results in changing the taste of the material, that is, in improving it to any desired extent, and in browning the material, which coloring effect is different from that produced on

Verfahren zur Herstellung von Kaffee-Extrakten und Kaffee-Ersatzextrakten in Pulverform mit natürlichen geschmacklichen und aromatischen Eigenschaften

Dr. Max Rudolf Morgenthaler, Vevey, ist als Erfinder genannt worden

Bei der Herstellung von trockenen, löslichen Kaffee-Extrakten und Kaffee-Ersatzextrakten liegt bekanntlich die Hauptschwierigkeit darin, die geschmacklich wertvollen und aromatischen Inhaltstoffe des Kaffees bzw. Kaffee-Ersatzes in möglichst natürlicher Form zu erhalten.

Dieser Schwierigkeit wird gemäß dem schweizerischen Patent Nr. 201940 dadurch begegnet, daß man dem flüssigen Kaffee-Extrakt vor der Trocknung ein oder mehrere Kohlehydrate wie Maltose, Dextrose, Dextrine usw. in reinem Zustande zur Bindung der Aromastoffe zusetzt. Diese Kohlehydrate werden vorzugsweise aus Stärke oder stärkehaltigen Produkten in reinem Zustande hergestellt.

Es ist bekanntlich auch möglich, aus bereits ausgelaugtem Kaffeesatz oder Kaffee-Ersatzrückständen durch Säurehydrolyse oder Autolyse unter Verwendung von hohem Druck und hoher Temperatur reine neutrale Kohlehydrate nach zweckmäßiger Reinigung zu erhalten, welche die geschmacklichen und aromatischen Eigenschaften des Extraktes anläßlich seiner Überführung in Pulverform und im Fertigprodukt zu schützen vermögen.

Diese Kohlehydratzusätze wurden in verschiedenen Proportionen, vorzugsweise aber im Verhältnis 50 % Kaffeetrockenmasse zu 50 % Kohlehydrat, verwendet.

Obschon die Farbe, der Geschmack und das Aroma eines so hergestellten trinkfertigen Produkts ausschließlich von der Kaffeesubstanz bzw. Kaffee-Ersatzsubstanz herrühren und die zugesetzten Kohlehydrate nur als farb- und geruchlose und überdies in der trinkfertigen, normalen Verdünnung höchstens als schwach süße Begleitstoffe zu erkennen sind und also in keiner Weise Kaffee- oder Kaffee-Ersatzsubstanzen vortäuschen, wurden diese Produkte in der Folge als nicht reine Extrakte vom Markte zurückgezogen.

Vom Standpunkt der Lebensmittelkontrolle betrachtet, besteht nun aber ein normaler Kaffee-Aufguß aus löslichen Kaffeebestandteilen, die durch siedendes Wasser oder nach dem Expressoverfahren mit leichtem Überdruck dem Kaffee entzogen werden. Haushaltungsmäßig hergestellte Extrakte ergeben bekanntlich eine Ausbeute des Röstkaffees von etwa 15 bis 20 % und die extreme Auskochung desselben mit einer Übermenge von Wasser und langem Kochen eine solche von maximal etwa 25—30 %, je nach Kaffeesorte.

Die technische Entwicklung der Kaffee- und Kaffee-Ersatzmittelextraktion geht nun heute allgemein so weit, daß die natürliche Löslichkeitsgrenze beispielsweise des Kaffees bei etwa 80—100° C, vorzugsweise bei Siedetemperatur des Wassers durch Anwendung von hohem Druck und hoher Temperatur, welche bis etwa 200° C betragen kann, unter teilweiser Hydrolyse des Unlöslichen bis über 50 % überschritten wird, was analytisch ohne weiteres nachweisbar ist. Aus Röstkaffee wird dadurch beispielsweise statt der durchschnittlichen Ausbeute von etwa 25 % vielfach eine solche von 35—40 % und mehr erreicht.

Diese Verfahren erlauben freilich infolge der vorerwähnten Hydrolyse eine scheinbare Mehrausbeute an Kaffeesubstanz oder Kaffee-Ersatzsubstanz, jedoch werden diese unreinen, stark sauren Hydrolysenprodukte aus Kaffeesatz nicht mehr, wie dies möglich wäre, bis zu den reinen Kohlehydraten gereinigt, sondern im kontinuierlichen Durchfluß direkt dazu verwendet, den bereits bis zur normalen Löslichkeit in siedendem Wasser von etwa 25 % ausgebeuteten, qualitativ normalen Kaffee-Extrakt einfach zu ver-

1

Bei der Herstellung von trockenen, löslichen Kaffee-Extrakten liegt bekanntlich die Hauptschwierigkeit darin, die geschmacklich wertvollen und aromatischen Inhaltstoffe des Kaffees in möglichst natürlicher Form zu erhalten.

Zu Anfang versuchte man dieser Schwierigkeit dadurch zu begegnen, daß man dem flüssigen Kaffee-Extrakt vor der Trocknung ein oder mehrere Kohlehydrate, z. B. Maltose, Dextrose, Dextrine in reinem Zustand, zur Bindung der Aromastoffe zusetzte. Diese Kohlehydrate wurden vorzugsweise aus Stärke oder stärkehaltigen Produkten in reinem Zustande hergestellt.

Es ist bekanntlich auch möglich, aus bereits ausgelaugtem Kaffeesatz durch Säurehydrolyse oder Autolyse unter Verwendung von hohem Druck und hoher Temperatur reine neutrale Kohlehydrate nach zweckmäßiger Reinigung zu erhalten, welche die geschmacklichen und aromatischen Eigenschaften des Kaffee-Extraktes bei dessen Überführung in Pulverform und im Fertigprodukt zu schützen vermögen.

Diese Kohlehydratzusätze wurden in verschiedenen Verhältnissen, vorzugsweise 50 % Kaffeetrockenmasse zu 50 % Kohlehydrat verwendet.

Obwohl in einer solchen Konserve die farblichen, geschmacklichen und aromatischen Eigenschaften des trinkfertigen Produktes ausschließlich von der reinen Kaffeesubstanz herrühren und die Kohlehydrate nur als farb- und geruchlose und überdies in der trinkfertigen, normalen Verdünnung höchstens als schwach süße Begleitstoffe zu erkennen sind und also in keiner Weise Kaffeesubstanz vortäuschen, wurden diese Produkte in der Folge als nicht reine Kaffee-Extrakte vom Markte zurückgezogen.

Vom Standpunkt der Lebensmittelkontrolle betrachtet, besteht ein normaler Kaffee-Aufguß aus löslichen Kaffeebestandteilen, die durch siedendes Wasser oder nach dem Expressoverfahren unter leichtem Überdruck dem Kaffee entzogen werden. Haushaltungsgemäß hergestellte Extrakte ergeben bekanntlich eine Ausbeute des Röstkaffees von z. B. 15 bis 20 % und die extreme Auskochung mit einer Übermenge von Wasser und langem Kochen von höchstens etwa 25 bis 30 % je nach Kaffeesorte.

Die technische Entwicklung der Kaffee-Extraktion geht nun heute allgemein so weit, daß die natürliche Löslichkeitsgrenze des Kaffees bei etwa 90 bis 110° C durch Einwirkung von hohem Druck und hoher Temperatur durch Hydrolyse bis über 50 % überschritten wird, was analytisch ohne weiteres nachweisbar ist. Aus Röstkaffee wird dadurch statt der durchschnittlichen Ausbeute von etwa 25 % vielfach eine solche von 35 bis 40 % und mehr erreicht.

2

Diese Verfahren erlauben also infolge der Hydrolyse eine scheinbare Mehrausbeute an Kaffeesubstanz, jedoch werden diese unreinen, stark sauren Hydrolysenprodukte aus Kaffeesatz nicht mehr, wie dies möglich wäre, bis zu den reinen Kohlehydraten gereinigt, sondern im kontinuierlichen Durchfluß direkt dazu verwendet, den bereits bis zur normalen Löslichkeit in siedendem Wasser von etwa 25 % ausgebeuteten, qualitativ normalen Kaffee-Extrakt einfach zu verdünnen. Damit wird erreicht, daß das Trocken-Extraktgewicht pro Tasse unnatürlich erhöht wird.

Diese, für sich allein betrachtet, nachweisbar geschmacklich minderwertigen, stark sauren Hydrolysate von Kaffeesatz, die ein p_H von 3 bis 4 aufweisen können, sind normalerweise in einem reinen, trinkfertigen Kaffee von etwa 25%iger Löslichkeit nicht vorhanden, und es kann somit von einem 100%ig natürlichen, löslichen Kaffee-Extrakt nicht mehr gesprochen werden (Gordian, Kaffee- u. Tee-Markt, 4. Januar 1955, Wurziger »Zur Untersuchung von Röstkaffe und Kaffee-Extrakt«).

Die ungereinigten sauren Hydrolysenprodukte mindern die Kaffeequalität so stark, daß auch ein Zusatz von Kohlehydraten die Qualität des Extraktes nicht zu verbessern vermag. Die auf dem Markt befindlichen Produkte distanzieren sich somit ganz wesentlich von einem normalen Kaffee-Trockenextrakt bzw. von einer normalen Kaffeeinfusion.

Production of Fat from Oidium Lactis

Plant Visited

Biologisch Chemisch Gesellschaft m.b.H. C22/2056

Location

Bad Tölz

Date of Visit

11 and 15 Sep 45

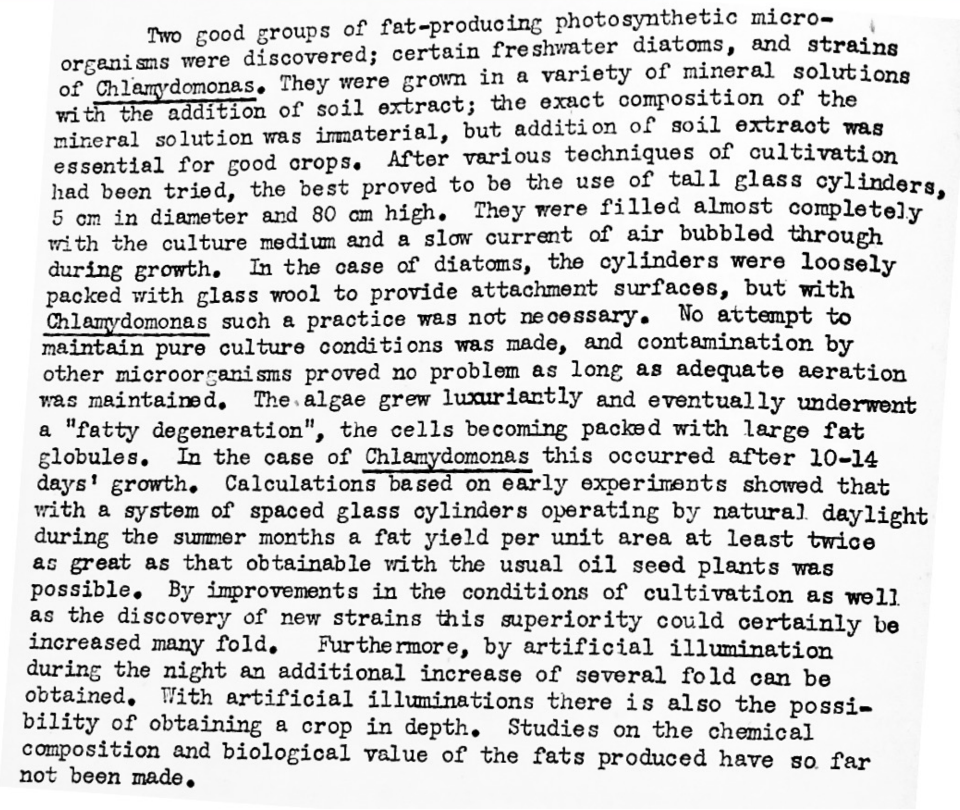
Object of Visit

To obtain information on the laboratory and pilot plant scale production of fat from OIDIUM LACTIS

Summary

The process showed some novel features with regard to the cultivation of a mould for high fat production and with regard to the combination of different types of waste material.used.

From cultured algae [BIOS 691]



Two good groups of fat-producing photosynthetic micro-organisms were discovered; certain freshwater diatoms, and strains of Chlamydomonas. They were grown in a variety of mineral solutions with the addition of soil extract; the exact composition of the mineral solution was immaterial, but addition of soil extract was essential for good crops. After various techniques of cultivation had been tried, the best proved to be the use of tall glass cylinders, 5 cm in diameter and 80 cm high. They were filled almost completely with the culture medium and a slow current of air bubbled through during growth. In the case of diatoms, the cylinders were loosely packed with glass wool to provide attachment surfaces, but with Chlamydomonas such a practice was not necessary. No attempt to maintain pure culture conditions was made, and contamination by other microorganisms proved no problem as long as adequate aeration was maintained. The algae grew luxuriantly and eventually underwent a "fatty degeneration", the cells becoming packed with large fat globules. In the case of Chlamydomonas this occurred after 10-14 days' growth. Calculations based on early experiments showed that with a system of spaced glass cylinders operating by natural daylight during the summer months a fat yield per unit area at least twice as great as that obtainable with the usual oil seed plants was possible. By improvements in the conditions of cultivation as well as the discovery of new strains this superiority could certainly be increased many fold. Furthermore, by artificial illumination during the night an additional increase of several fold can be obtained. With artificial illuminations there is also the possibility of obtaining a crop in depth. Studies on the chemical composition and biological value of the fats produced have so far not been made.

Figure 3.61: In the 1930s and early 1940s, German-speaking scientists developed methods to produce fats via biotechnology using cultured yeast or algae cells [BIOS 236; BIOS 691].

3.3.4 Synthetic Protein Products

Likewise in the 1930s and early 1940s, German-speaking scientists developed several egg protein substitutes that consisted of protein extracted and processed on an industrial scale from (Fig. 3.62):

- Cultured strains of yeast that produced the variety of amino acids needed by humans, as developed by Andreas Lembke (German, 1911–2002) and other scientists [BIOS 236; BIOS 691; FIAT 491].
- Animal blood plasma (a final product called Plenora), as developed by scientists at the Rugamer & Co. Plenora-Werke in Hamburg [BIOS 1417; FIAT 491].
- Fish (a final product called Eiweiss), as developed by Peter Paul Hiltner (German, 19??–19??) and other scientists [BIOS 1481; FIAT 491].
- Milk (a final product called Milei), as developed by Georg Demmler (German, 19??–19??) and other scientists [BIOS 32; BIOS 275; BIOS 1513; BIOS 1782; FIAT 491].

3.3.5 Preservatives

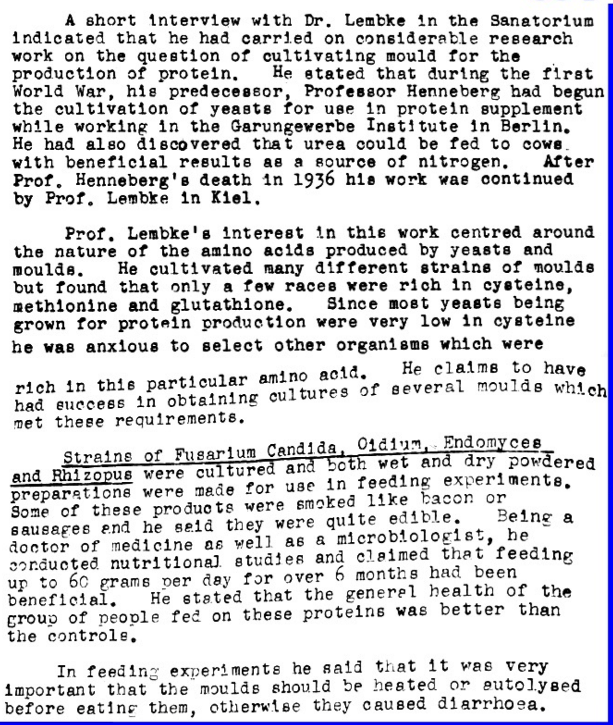
In order to preserve valuable food stocks for storage and transport during both peacetime and wartime, German-speaking scientists developed many important food preservatives that work by chelating (trapping) metal ions that are needed by degradative enzymes and bacteria. These preservatives have been widely used ever since, and include for example:

- Ascorbic acid (vitamin C), which was identified in 1930 by Albert Szent-Györgyi (Hungarian, 1893–1986) and mass-produced via chemical synthesis in 1933 by Tadeusz Reichstein (Polish, educated and worked in Switzerland, 1897–1996, Fig. 3.63).
- Benzoic acid, which was first analyzed in 1832 by Friedrich Wöhler (German, 1800–1882) and Justus von Liebig (German, 1803–1873, Fig. 3.63).
- Citric acid, which was first produced from fermentation in fungi in 1890 by Carl Wehmer (German, 1858–1935, Fig. 3.63) [Benninga 1990, p. 140].
- Sorbic acid, which was discovered in 1859 by August Wilhelm von Hofmann (German, 1818–1892, Fig. 3.63).
- Ethylenediaminetetraacetic acid (EDTA), an extremely effective chelator, which was synthesized and demonstrated in 1935 by Ferdinand Münz (Austrian, 1888–1969, Fig. 3.64) Schahinian 2018.

In 1940, German-speaking scientists also developed and successfully implemented the use of ultraviolet light to sterilize drinks so that they could be packaged for safe long-term storage without requiring refrigeration [BIOS 770; FIAT 50; FIAT 107; FIAT 257]. Some of the most important scientists in the project were Andreas Lembke (German, 1911–2002), Hellmuth Bayha (German?, 19??–19??), Karl Krammer (German?, 19??–19??), and Eugen Sauter (German?, 19??–19??). For more information, see pp. 2367–2373.

Artificial egg protein

Protein derived from cultured yeast [BIOS 236]



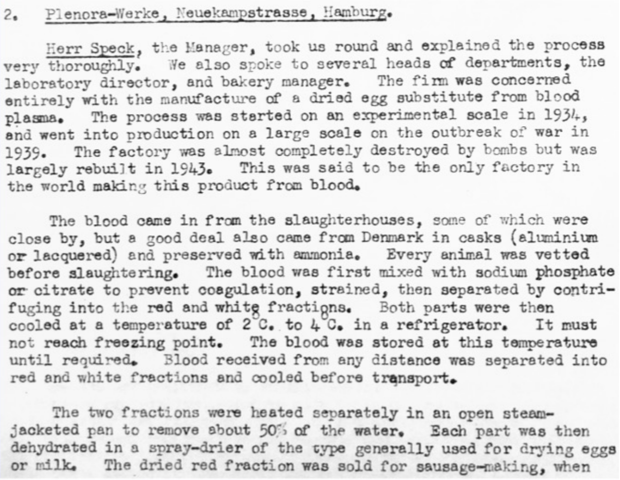
A short interview with Dr. Lembke in the Sanatorium indicated that he had carried on considerable research work on the question of cultivating mould for the production of protein. He stated that during the first World War, his predecessor, Professor Henneberg had begun the cultivation of yeasts for use in protein supplement while working in the Garungewerbe Institute in Berlin. He had also discovered that urea could be fed to cows with beneficial results as a source of nitrogen. After Prof. Henneberg's death in 1936 his work was continued by Prof. Lembke in Kiel.

Prof. Lembke's interest in this work centred around the nature of the amino acids produced by yeasts and moulds. He cultivated many different strains of moulds but found that only a few races were rich in cysteine, methionine and glutathione. Since most yeasts being grown for protein production were very low in cysteine he was anxious to select other organisms which were rich in this particular amino acid. He claims to have had success in obtaining cultures of several moulds which met these requirements.

Strains of Fusarium Candida, Oidium, Endomyces and Rhizopus were cultured and both wet and dry powdered preparations were made for use in feeding experiments. Some of these products were smoked like bacon or sausages and he said they were quite edible. Being a doctor of medicine as well as a microbiologist, he conducted nutritional studies and claimed that feeding up to 60 grams per day for over 6 months had been beneficial. He stated that the general health of the group of people fed on these proteins was better than the controls.

In feeding experiments he said that it was very important that the moulds should be heated or autolysed before eating them, otherwise they caused diarrhoea.

Plenora derived from animal blood plasma [BIOS 1417]



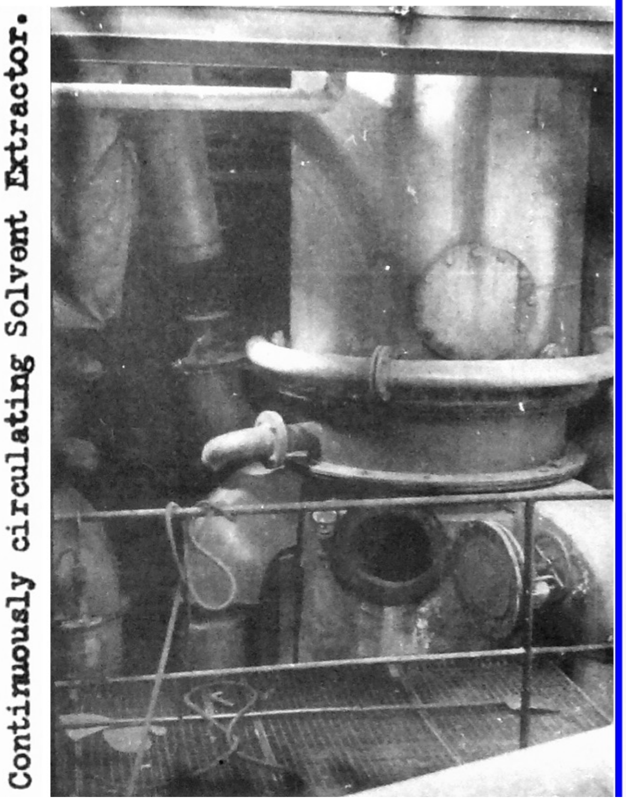
2. Plenora-Werke, Neuekampstrasse, Hamburg.

Herr Speck, the Manager, took us round and explained the process very thoroughly. We also spoke to several heads of departments, the laboratory director, and bakery manager. The firm was concerned entirely with the manufacture of a dried egg substitute from blood plasma. The process was started on an experimental scale in 1934, and went into production on a large scale on the outbreak of war in 1939. The factory was almost completely destroyed by bombs but was largely rebuilt in 1943. This was said to be the only factory in the world making this product from blood.

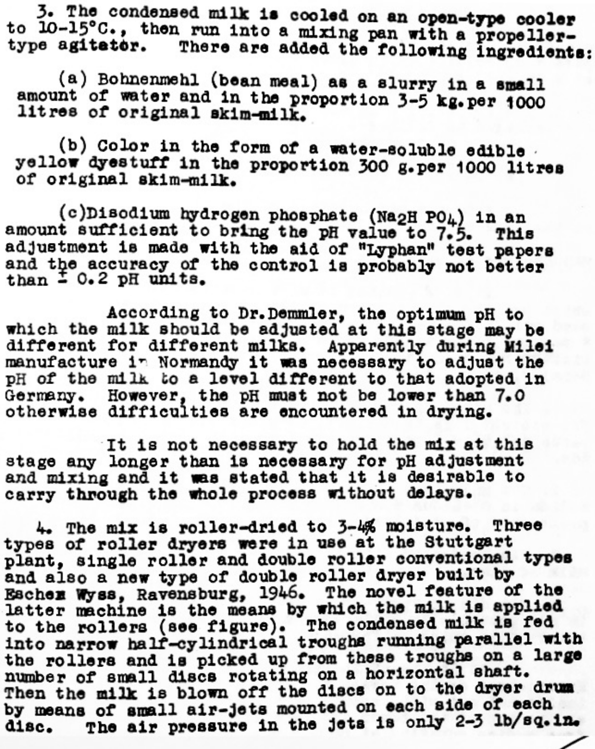
The blood came in from the slaughterhouses, some of which were close by, but a good deal also came from Denmark in casks (aluminium or lacquered) and preserved with ammonia. Every animal was vetted before slaughtering. The blood was first mixed with sodium phosphate or citrate to prevent coagulation, strained, then separated by contrifuging into the red and white fractions. Both parts were then cooled at a temperature of 2°C. to 4°C. in a refrigerator. It must not reach freezing point. The blood was stored at this temperature until required. Blood received from any distance was separated into red and white fractions and cooled before transport.

The two fractions were heated separately in an open steam-jacketed pan to remove about 50% of the water. Each part was then dehydrated in a spray-drier of the type generally used for drying eggs or milk. The dried red fraction was sold for sausage-making, when

Eiweiss derived from fish [BIOS 1481]



Milei derived from milk [BIOS 1513]



3. The condensed milk is cooled on an open-type cooler to 10-15°C., then run into a mixing pan with a propeller-type agitator. There are added the following ingredients:-

(a) Bohnenmehl (bean meal) as a slurry in a small amount of water and in the proportion 3-5 kg.per 1000 litres of original skim-milk.

(b) Color in the form of a water-soluble edible yellow dyestuff in the proportion 300 g.per 1000 litres of original skim-milk.

(c)Disodium hydrogen phosphate ($Na_2H\ PO_4$) in an amount sufficient to bring the pH value to 7.5. This adjustment is made with the aid of "Lyphan" test papers and the accuracy of the control is probably not better than ± 0.2 pH units.

According to Dr.Demmler, the optimum pH to which the milk should be adjusted at this stage may be different for different milks. Apparently during Milei manufacture in Normandy it was necessary to adjust the pH of the milk to a level different to that adopted in Germany. However, the pH must not be lower than 7.0 otherwise difficulties are encountered in drying.

It is not necessary to hold the mix at this stage any longer than is necessary for pH adjustment and mixing and it was stated that it is desirable to carry through the whole process without delays.

4. The mix is roller-dried to 3-4% moisture. Three types of roller dryers were in use at the Stuttgart plant, single roller and double roller conventional types and also a new type of double roller dryer built by Escher Wyss, Ravensburg, 1946. The novel feature of the latter machine is the means by which the milk is applied to the rollers (see figure). The condensed milk is fed into narrow half-cylindrical troughs running parallel with the rollers and is picked up from these troughs on a large number of small discs rotating on a horizontal shaft. Then the milk is blown off the discs on to the dryer drum by means of small air-jets mounted on each side of each disc. The air pressure in the jets is only 2-3 lb/sq.in.

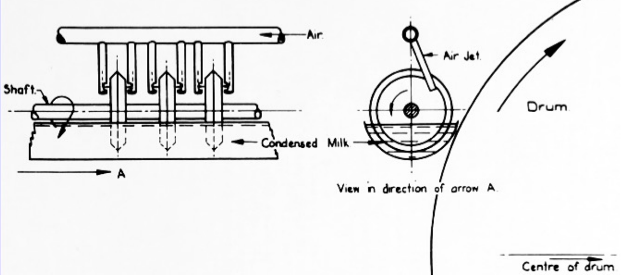


Figure 3.62: In the 1930s and early 1940s, German-speaking scientists developed several egg protein substitutes that consisted of protein extracted and processed on an industrial scale from cultured yeast, animal blood plasma (Plenora), fish (Eiweiss), and milk (Milei) [BIOS 236; BIOS 1417; BIOS 1481; BIOS 1513].

3.4 Explosives

Scientists from the German-speaking world were responsible for most of the major innovations in modern explosives, including:[8]

3.4.1. Explosive chemical compounds

3.4.2. Fuel-air explosives

3.4.3. Shaped explosive charges

3.4.4. Radio control and electric timers for explosives

3.4.1 Explosive Chemical Compounds

German-speaking chemists developed most of the major modern explosive chemical compounds.

The first known high explosive was fulminating gold, a complex mixture of compounds containing gold, ammonia, and chlorine. Fulminating gold was produced and demonstrated by Sebalt Schwertzer (German states, 1552–1598) and Johann Thölde/Thölden (German states, 1565–1614). Historical portraits of Schwertzer and Thölde(n) do not appear to exist, but Fig. 3.65 shows illustrations of typical alchemists from that time and place.

As illustrated in Fig. 3.66, Christian Schönbein (German states, 1799–1868), Rudolf Christian Böttger (German, 1806–1881), Friedrich Julius Otto (German, 1809–1870), and Wilhelm Lenk von Wolfsberg (Austrian, 1809–1894) developed nitrocellulose or guncotton explosive.

Johann F. E. Schultze (German?, 18??–19??), Max Duttenhofer (German, 1843–1903), and Frederick Volkmann (German?, 18??–19??) developed smokeless powder, shown in Fig. 3.67. Smokeless powder is essentially an improved nitrocellulose material in flake or powder form, and has been widely used as propellant for small solid rockets.

Johann Rudolf Glauber (German states, 1604–1670) discovered picric acid around 1648, and Hermann Sprengel (German states, 1834–1906) produced large quantities of picric acid as an explosive in 1871 (Fig. 3.68). Sprengel also produced safety explosives (binary explosives that can be safely stored as separate components, then mixed shortly before use) and other explosive-related products.

As shown in Fig. 3.69, Julius Wilbrand (German, 1839–1906) first synthesized trinitrotoluene (TNT) in 1863, Paul Hepp (German, 18??–19??) improved the synthesis in 1880, and Karl Häussermann (German, 1853–1918) used TNT as an explosive in 1889. Science historian Peter Krehl described their contributions [Krehl 2009, p. 404]:

---

[8] George Brown 1998; Field 2017; Kennedy 1990; Krehl 2009; Walters and Zukas 1989.

> 1891: Karl Häussermann, a German chemist, discovers the explosive properties of trinitrotoluene [...], later known as TNT. The substance was first crudely synthesized by the German chemist Julius Wilbrand [...]; pure TNT was first prepared by the German chemist Paul Hepp in 1880. Häussermann, who undertook the manufacture of TNT on an industrial scale, was also the first to suggest its military use: pressed into shells, it can withstand the shock developed by the propellant when a shell is fired from a gun barrel. In 1902, TNT was adopted for use by the German army.

The chemist and chemical historian Aaron Ihde added [Ihde 1984, p. 706]:

> During World War I TNT and picric acid explosives were brought into large-scale use. The Germans, with their flourishing coal tar chemicals industry, were prepared for the production of high explosives. The French and British were not nearly as well prepared.

Wilhelm Michler (German, 1846–1889), Carl Meyer (German, 18??–19??), Karel Hendrik Mertens (Dutch, 18??–19??), and Pieter van Romburgh (Dutch, 1855–1945) developed tetryl explosive beginning in 1877 (Fig. 3.70). The chemist Simon Field summarized the story [Field 2017, pp. 81–82]:

> In 1877, German chemists Wilhelm Michler and Carl Meyer invented the compound tetryl, or 2,4,6-trinitrophenylmethylnitramine. It took until 1886 before its structure was established by Dutch chemist Karel Hendrik Mertens. Another Dutch chemist, Pieter van Romburgh later (in 1889) proved the structure by synthesizing it from picryl chloride and potassium methylnitramine.
>
> Tetryl was the first of the nitramine class of high explosives, which includes many of the most explosive compounds currently in use. [...] Nitramines are characterized by the two nitrogen atoms connected together, with one of them then connected to two oxygen atoms.
>
> Tetryl was used in both World Wars as a booster, and by itself in some of the smaller caliber shells.

As illustrated in Fig. 3.71, Georg Friedrich Henning (German, 1863–1945) first synthesized hexogen in 1898, and Edmund von Herz (German, 18??–19??) patented hexogen as an explosive in 1919. Hexogen was named for its six-sided central ring, surrounded by three symmetrical nitro groups. Later it became much more widely known as "Research Department Explosive" or RDX in the United Kingdom and United States. During the Third Reich, German chemists extended the approach of hexogen to create octogen, an eight-sided central ring with four symmetrical nitro groups. Octogen later became better known as HMX.

Figure 3.72 shows that nitroglycerin and dynamite were also closely connected to the German-speaking research world. Ascanio Sobrero (Italian but studied under Justus Liebig, 1812–1888) developed nitroglycerin explosive in 1847. Nitroglycerin is extremely powerful but quite sensitive to physical shock. In 1867, Alfred Nobel (Swedish but worked in Germany, 1833–1996) developed dynamite, which is clay soaked with nitroglycerin, in order to make the nitroglycerin less sensitive to shock and therefore much easier to transport and use.

Bernhard Tollens (German, 1841–1918) and Peter Wigand (German, 18??–19??), shown in Fig. 3.73, developed pentaerythritol tetranitrate (PETN) explosive in 1891. The general public nowadays is more familiar with Semtex plastic explosive, which is a mixture of PETN and RDX with a small amount of plasticizer and binder. PETN is also used as a blood pressure medication.

Figure 3.74 presents examples of German-speaking scientists who made important contributions to the mathematical theory of explosions. Walther Nernst (German, 1864–1941) and Max Bodenstein (German, 1871–1942) worked out the theory of explosive chain reactions; Nernst won the Nobel Prize in Chemistry in 1920 (p. 913). Heinrich Mache (Austrian, 1876–1954) and Ludwig Flamm (Austrian, 1885–1964) developed the theory of explosive gas mixtures.

Over two years after World War II ended in Europe, the U.S. War Department General Staff (WDGS) Intelligence Division wrote a report summarizing what they had learned about "New Explosives Developed by the Germans" during the war. Even after so many decades, that report remains classified and unavailable to the public. Why? What new explosive compounds or methods were described in that report, or in others like it that may still be buried in classified archives? See Fig. 3.75.

UNITED STATES PATENT OFFICE.

EDMUND VON HERZ, OF CHARLOTTENBURG, GERMANY.

EXPLOSIVE.

1,402,693. Specification of Letters Patent. Patented Jan. 3, 1922.

No Drawing. Application filed October 25, 1920. Serial No. 419,417.

To all whom it may concern:

Be it known that Edmund von Herz, a citizen of Germany, residing at 29 Sybelstrasse, Charlottenburg, Germany, formerly of 48 Schoubergerstrasse, Vienna, Austria, has invented certain new and useful Improvements Relating to Explosives, (for which I have filed an application in Austria, Jan. 25, 1919,) of which the following is a specification.

The well known nitro explosives used in practice belong both as regards their chemical constitution and also their properties and effects in general to two different groups, viz. the ethereal salts of nitric acid and the nitro compounds proper. Typical representatives of the first class are nitro glycerine and guncotton, of the second the aromatic nitro compounds such as trinitrotoluene, picric acid and tetranitromethylaniline. The most prominent features of the ethereal salts of nitric acid are on the favourable side the high amount of energy they contain and on the unfavourable side their easy liability to decomposition and their extraordinarily great sensitiveness towards mechanical influences. In contradistinction hereto is the behaviour of the aromatic nitro compounds. Their advantages are in particular their extraordinary chemical stability and their marked non-sensitiveness towards shock, but their disadvantage is their comparatively low energy.

These oppositely contracted properties explain the various attempts which have been made to provide an explosive, which shall combine in itself only the advantages of both classes of explosive, that is to say a compound, which, in addition to the stability and non-sensitiveness of the aromatic nitro compounds exhibits the degree of energy of the ethereal salts of nitric acid. As a result of these attempts hitherto obtained, certain tetranitrated benzene derivatives with the only recently prepared tetranitraniline are the chief. These compounds are most certainly an advance in this direction, but they have not fulfilled the expectations demanded of them, because, as it was subsequently found, the increase in energy conferred by the fourth nitro group was obtained at the expense of a serious decrease in their stability. Owing to a decided liability of the fourth nitro group, which is situated in the meta position, these highly nitrated substances are so liable to decomposition, that any practical use thereof is not to be thought of.

In this way therefore the end aimed at cannot be attained and there are consequently at present no prospects of the realization of this idea.

Now according to the present invention it has been found that hexamethylenetetramine, the well known condensation product obtained from formaldehyde and ammonia, yields, when suitably treated with concentrated nitric acid, an extraordinarily powerful explosive compound, which combines in itself in an absolutely ideal manner the favourable properties of the ethereal salts of nitric acid and the aromatic nitro compounds.

This new explosive substance is neither an ethereal salt of nitric acid nor a pure nitro compound, but is a nitramine with a peculiar ring formation. As chemical investigation has shown, it is derived like hexamethylenetetramine from the hypothetical cyclotrimethylenetriamine

and possesses the following structural formula:

This cyclotrimethylenetrinitramine is formed from all the accessible derivatives of cyclotrimethylenetriamine by the action of concentrated nitric acid. For its production on a large scale, however, only cyclotrimethylenetrimethyltriamine, that is the condensation product obtained from formaldehyde with methylamine could be entertained as a raw material in addition to the already known hexamethylenetetramine, as the other derivatives are difficultly accessible and therefore not economical.

The following method of preparation has

No. 3826 — New Explosives Developed — By The Germans

Figure 3.75: Over two years after World War II ended in Europe, the U.S. War Department General Staff (WDGS) Intelligence Division wrote a report summarizing what they had learned about "New Explosives Developed by the Germans" during the war. Even after so many decades, that report remains classified and unavailable to the public. Why? What information is in the report? [NARA RG 319, Entry NM3-82, Box 2899, Folder Project 3826]

3.4.2 Fuel-Air Explosives

German-speaking scientists also invented and developed fuel-air explosives [von Haken 1933; Karlsch 2007b; Stevens 2007, pp. 103–111; CIOS ER 201]. While fuel-air explosives use conventional chemical explosive compounds, they disperse those explosive compounds widely before the detonation, and allow the compounds to combust with oxygen in the air. Therefore, fuel-air explosives can cause damage to a much larger area than would be possible with normally packaged bombs of the same explosive compounds.

The earliest known description of a fuel-air explosive bomb is a patent application filed on 6 April 1933 by Kurd von Haken (German?, 18??–19??), DE680483, Fliegerbombe für Kohlenstaubexplosionen [Airborne Bombs for Coal Dust Explosions] (Fig. 3.76):

> In der Zeichnung ist der Fliegerbombenkörper in Abb. 1 schematisch im Schnitt dargestellt. Abb. 2 betrifft ein offenes Fallschirmchen mit dem Zeitzünder. In Abb. 3 ist die Zeitwirkung der Explosion einer Gruppe solcher Bomben auf ein Druckwellenempfangsgerät auf der Seite in einiger Entfernung dargestellt. Es bedeutet 4 die Bombe mit Kohlenstaub, gegebenenfalls mit flockig in diesem verteilten Feuerwerkpulversätzen, 5 ein etwa barometrisch einstellbares Gerät zum Auslösen des Fallschirmes, 6 die durch irgendein an sich bekanntes Mittel von mehreren Flugzeugen aus für alle Bomben gleichzeitig einzustellende Zündvorrichtung, die zu den einzelnen Zündern 7 führt, die mit etwa mittels einer Taschenlampenbatterie 8 auszulösende Zeitzünderchen 9 versehen sind. Die Zeitzünderchen 9 sind von den von ihnen zu zündenden Zündsätzen für den Kohlenstaub 10 umgeben, an die ein sie zerstäubender Sprengstoffkörper 11 sich anschließt. 12 ist das Fallschirmchen für diese Zeitzünder, die in zusammengelegtern Zustande in besonderen Kammern 13 der leicht zu zerteilenden Bombe angeordnet sind. 14 ist der Initialsprengkörper zum Zerstäuben der ganzen Bombe. 15 ist ein Fallschirm, gegebenenfalls mit propellerförmig angeordneten Öffnungen 16 versehen, damit die Bombe in Drehung gerät und so in begrenztem Maße durch die Schwingungen der Fallschirme gehemmt wird. 12' ist das Fallschirmchen mit dem Zeitzünder in geöffnetem Zustande.

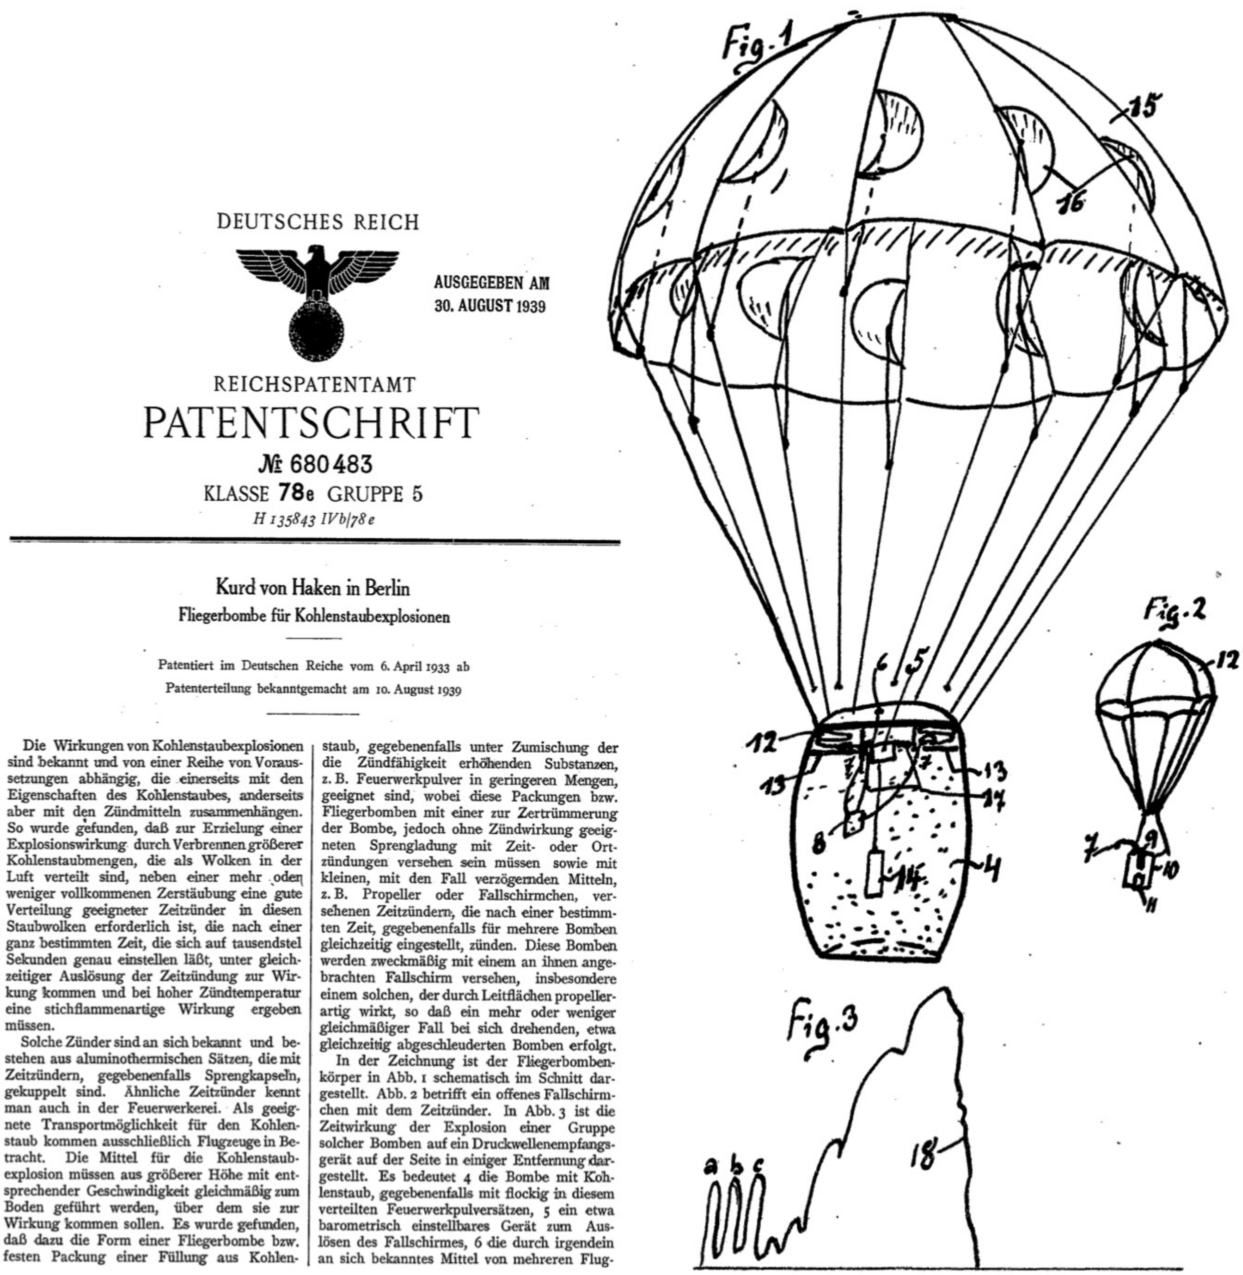
> In the drawing, the aerial bomb is shown schematically in section in Fig. 1. Fig. 2 concerns an open parachute with the time fuse. Figure 3 shows the time effect of the explosion of a group of such bombs on a pressure wave receiving device on the side at some distance. 4 means the bomb with pulverized coal dust, possibly with a flare in the distributed fireworks powder etching, 5 an approximately barometrically adjustable device for triggering the parachute, 6 which, by means of a means known per se from a plurality of airplanes, which are provided with timers 7 to be triggered by means of a torch battery 8, for example. The timers 9 are of the ignitions to be lit by them. For the carbon dust 10, to which an explosive body, which atomizes them, follows. 12 is the parachute for these time igniters, which are arranged in a combined state in particular chambers 13 of the easy-to-split bomb. 14 is the atomic bubble for atomizing the whole bomb. 15 is a parachute, provided if necessary with propeller-shaped openings 16, so that the bomb is turned and thus limited to a certain degree by the vibrations of the parachutes. 12' is the parachute with the time fuse in the opened state.

Beim etwa gleichzeitigen Abwurf einer Reihe von Bomben öffnen sich nicht alle Bombenfallschirme gleichzeitig, so daß die Bomben in verschiedener Höhe und in verschiedener Zeit über einer mehr oder weniger großen Zielfläche, z.B. 1 qkm, verteilt sind, im Gesamtgewicht von etwa 10 t. Bei der Primärzerstäubungdurch Zünden der Sprengkörper 14 bilden sich um die Bomben eine Reihe Staubwolken, die in langsamem Falle weiter sinken. Die kleinen Fallschirmchen mit den kleinen Zeitzündern öffnen sich gleichzeitig oder früher durch Auslösung einex Hilfsvorrichtung 17 vom Manometer aus und verteilen sich in gleichmäßigem Falle in diesen Staubwolken, so daß sie auch annähernd gleichzeitig zur Explosion kommen. Auf dem Zeitmeßgerät zeichnen sich dann, je nach der Entfernung der Bomben 1, 2, 3 und der Zündkörperchen 1 bis 10, drei Wellen *a, b, c* für die Zerstäubung und etwa fünf kleine Wellen, von der Explosion der Zündkörperchen herrührend, ab. Um die detonierenden Zündkörperchen herum wirkt sich progressiv steigernd eine große Druckwelle 18 aus, die im Zusammenhang mit der Großluftbewegung mit Überschallgeschwindigkeit auf große Entfernung zur Wirkung gelangt.

When a series of bombs are dropped at the same time, not all of the bombshells open at the same time, so that the bombs are at different heights and at different times over a more or less large target area, for example, 1 square kilometer, with a total weight of approximately 10 t. In primary sputtering by igniting the explosive bodies 14, a series of dust clouds form around the bombs, which sink further in a slow case. The little parachutes with the small time fuses open at the same time or earlier by triggering an auxiliary device from the manometer and distributing themselves in this case evenly in the dust clouds, so that they also almost explode at the same time. According to the distance of the bombs 1, 2, 3 and the ignition body 1 to 10, three waves *a, b, c* for the atomization and about five small waves, which originate from the explosion of the ignition cores, are then distinguished on the time-measuring device. Around the detonating detonators, a large pressure wave 18 acts progressively increasing, which in conjunction with the shock wave arrives at a great distance with a supersonic velocity.

Currently it is not clear what role (if any) Kurd von Haken played in the subsequent development and testing of his ideas for fuel-air explosives.

Kurd von Haken (18??–19??) invented fuel-air explosives



DEUTSCHES REICH

AUSGEGEBEN AM
30. AUGUST 1939

REICHSPATENTAMT
PATENTSCHRIFT
№ 680483
KLASSE 78e GRUPPE 5
H 135843 IVb/78e

Kurd von Haken in Berlin
Fliegerbombe für Kohlenstaubexplosionen

Patentiert im Deutschen Reiche vom 6. April 1933 ab
Patenterteilung bekanntgemacht am 10. August 1939

Die Wirkungen von Kohlenstaubexplosionen sind bekannt und von einer Reihe von Voraussetzungen abhängig, die einerseits mit den Eigenschaften des Kohlenstaubes, anderseits aber mit den Zündmitteln zusammenhängen. So wurde gefunden, daß zur Erzielung einer Explosionswirkung durch Verbrennen größerer Kohlenstaubmengen, die als Wolken in der Luft verteilt sind, neben einer mehr oder weniger vollkommenen Zerstäubung eine gute Verteilung geeigneter Zeitzünder in diesen Staubwolken erforderlich ist, die nach einer ganz bestimmten Zeit, die sich auf tausendstel Sekunden genau einstellen läßt, unter gleichzeitiger Auslösung der Zeitzündung zur Wirkung kommen und bei hoher Zündtemperatur eine stichflammenartige Wirkung ergeben müssen.

Solche Zünder sind an sich bekannt und bestehen aus aluminothermischen Sätzen, die mit Zeitzündern, gegebenenfalls Sprengkapseln, gekuppelt sind. Ähnliche Zeitzünder kennt man auch in der Feuerwerkerei. Als geeignete Transportmöglichkeit für den Kohlenstaub kommen ausschließlich Flugzeuge in Betracht. Die Mittel für die Kohlenstaubexplosion müssen aus größerer Höhe mit entsprechender Geschwindigkeit gleichmäßig zum Boden geführt werden, über dem sie zur Wirkung kommen sollen. Es wurde gefunden, daß dazu die Form einer Fliegerbombe bzw. festen Packung einer Füllung aus Kohlenstaub, gegebenenfalls unter Zumischung der die Zündfähigkeit erhöhenden Substanzen, z. B. Feuerwerkpulver in geringeren Mengen, geeignet sind, wobei diese Packungen bzw. Fliegerbomben mit einer zur Zertrümmerung der Bombe, jedoch ohne Zündwirkung geeigneten Sprengladung mit Zeit- oder Ortzündungen versehen sein müssen sowie mit kleinen, mit den Fall verzögernden Mitteln, z. B. Propeller oder Fallschirmchen, versehenen Zeitzündern, die nach einer bestimmten Zeit, gegebenenfalls für mehrere Bomben gleichzeitig eingestellt, zünden. Diese Bomben werden zweckmäßig mit einem an ihnen angebrachten Fallschirm versehen, insbesondere einem solchen, der durch Leitflächen propellerartig wirkt, so daß ein mehr oder weniger gleichmäßiger Fall bei sich drehenden, etwa gleichzeitig abgeschleuderten Bomben erfolgt.

In der Zeichnung ist der Fliegerbombenkörper in Abb. 1 schematisch im Schnitt dargestellt. Abb. 2 betrifft ein offenes Fallschirmchen mit dem Zeitzünder. In Abb. 3 ist die Zeitwirkung der Explosion einer Gruppe solcher Bomben auf ein Druckwellenempfangsgerät auf der Seite in einiger Entfernung dargestellt. Es bedeutet 4 die Bombe mit Kohlenstaub, gegebenenfalls mit flockig in diesem verteilten Feuerwerkpulversätzen, 5 ein etwa barometrisch einstellbares Gerät zum Auslösen des Fallschirmes, 6 die durch irgendein an sich bekanntes Mittel von mehreren Flug-

Figure 3.76: Kurd von Haken filed a patent application on fuel-air explosives in 1933.

Using von Haken's patent, Mario Zippermayr (Austrian, 1899–1979) and other scientists developed and tested fuel-air explosives during World War II, as shown in Figs. 3.77–3.90 [CIOS ER 201, NavTecMisEu 548-45]. Historian Rainer Karlsch explained the development program [Karlsch 2007b]:

> During the war a group of scientists under the direction of the Austrian physicist Mario Zippermayr made use of the patent belonging to Kurd von Haken. They improved the concept of the coal dust bomb. [...]
>
> Zippermayr's activities for the Air Force and the establishment of his research institute probably did not begin until 1942. The swift progress of the group is therefore even more astounding. Zippermayr was not, however, the scientific "brain" of the group, but rather its loyal Nazi manager.
>
> According to reports by the US Forces Austria Counter-Intelligence Corps, his group had 35 individuals employed in locations in Vienna and in Lofer, Tyrol. The most important research project was the development of a highly explosive warhead with which the anti-aircraft missiles 'Enzian' (Gentian) and 'Schmetterling' (Butterfly) were to be fitted.
>
> The project work was accelerated in the second half of 1944, after the landing of the Allies at Normandy and the assassination attempt on Hitler. At that point the SS took over the most modern weapons development projects, and tried to bring these weapons to a usable stage of development. Among the many exotic ideas there were also some technically very demanding projects such as the development of nerve gases, missiles and nuclear explosives.
>
> Himmler's organization also had an influence on the project of SS officer Mario Zippermayr, and in this case the cooperation between researchers and the SS was probably especially close. The researchers were on a promising path, as Zippermayr reported in October 1944 in a report for the Reichsforschungsrat (Research Advisory Council) labeled "Geheime Kommandosache" (Secret Commando Matter). He referred to experiments that took place in the spring of 1943 with 60 kilograms of a mixture of coal dust and liquid oxygen in the vicinity of the air base Zwölfaxing near Vienna. The explosions broke windows up to 1.5 kilometers away. As far as 3.5 kilometers away, windows and doors that had been pulled to were pushed open by the explosions.
>
> The project was given the code name "Witches Cauldron" [Hexenkessel]. Contributors to the project were scientists from Dynamit Nobel Corporation, Rheinmetall-Borsig, the Ballistic Institute in Gatow, as well as specialists from the brown coal industry and from the Zippermayr group. Probably there was at least one more SS research group that conducted similar experiments in Silesia and in other locations.
>
> According to information that reached British intelligence early in 1945, a test north of Berlin achieved a destructive radius of approximately 600 meters. The heat and pressure wave ignited trees in the target area and knocked them over. The air force could have made good use of such a weapon. The plan was to target these at aircraft formations via anti-aircraft missiles. As far as we know, these missiles were never used, however.

> But the new bomb could have been used against large surface target areas. This was a very real danger. According to American secret service reports, the German military possessed at war's end 5-ton "liquid air bombs," as the thermobaric bombs were called then. In the National Archive in Washington, there is a document naming a plant in Nordhausen, in the Harz region, where the V-2 missiles were produced, as the location for the production of even larger "oxygen bombs" (yet another name for these same bombs). [See pp. 556–557.] An actual use of the bombs never occurred.
>
> Even as late as the capitulation, the victors possessed only vague secret service information about the super bomb. Nevertheless, there was an interest in the immediate study and development of this technology, of course under conditions of utmost secrecy. For this reason, Zippermayr was repeatedly questioned by the Chemical Warfare Service, beginning on 3 August 1945. During a later interrogation in 1949, he told the Americans that with his bomb—whether with pulverized coal dust or with gas or other liquids—he could achieve the area destruction of a small atomic bomb. Furthermore, the production of such a bomb would be much cheaper.
>
> In contrast to other prominent German weapons industry researchers, there was reluctance to transport the SS man Zippermayr to the United States. However, several of his colleagues were offered the opportunity to continue their research in America in the context of "Operation Paperclip." Apparently the Soviets also benefited from the knowledge produced by the Zippermayr group. According to an American report, Heinrich Mache, a professor at the Technical University in Vienna, was forced to conduct experiments with coal dust explosives in October 1945 under Soviet supervision.
>
> The terrible fruits of the Zippermayr group did not just remain in the arsenals. They were used as "enhanced blast weapons" in the Vietnam War and in 1969 in Soviet-Chinese border conflicts at the Ussuri River. This name comes from the fact that the temperatures achieved by these bombs were not extreme. This changed in the late 1980s when the reaction temperature was raised substantially through added metallic particles, primarily aluminum, but also through other metals, as well as through oxygen. The principle of the thermobaric bomb, however, remained the same and is one example for the fact that it was not just in the case of missiles and jet planes that the victors in the Second World War made use of the knowledge of the defeated powers. That the technology behind the "father of all bombs" is old hat should not obscure the fact that this is a weapon of mass destruction that should be forbidden.

Note that the use of powdered aluminum in explosives to enhance the temperature and blast (as described above) was also developed in wartime Germany; see pp. 5692–5695 [BIOS 27; BIOS 100; BIOS 1261]. Thus the "thermobaric" and "enhanced blast weapons" built by the United States and other countries after the war were entirely derived from technologies that had previously been designed and demonstrated in Germany and Austria, based on information and materials obtained from German-speaking scientists, as well as the direct assistance of many of those scientists themselves (as shown below).

An August 1949 JIOA document, Immigration of Austrian Scientists to Soviet Zone, listed several key members of Zippermayr's team [NARA RG 319, Entry A1-134A, Box 31, Folder 02/006 430]:

> FRITSCHE, Doz. Dr. Ing. Volker, Technische Hochschule, Vienna. Formerly with the Zippermayr Laboratory engaged in research in use of coal dust as antiaircraft explosive. Member of the Electro-technical Institute, Technische Hochschule. Reportedly making survey for Russians on high frequency prospecting for oil.
>
> HOENIG, Dr Alfred, Scheffsnoth 8, Zell am See, Austria. Formerly worked at Zippermayr Institute engaged in research on coal dust explosives. Chemical Corps and Air Corps interestd. Chemical expert interviewed subject and ZIPPERMAYER, and agreed that their theories were basically sound and could not be permitted to reach potential U.S. enemies. It will be recommended that these two with KILLIAN be employed in U. S. HOENIG fears that he might be kidnapp[blacked out]
>
> KILLIAN, Karl, Hattlegasse 40, Hitzing, Vienna XIII, Austria. Mathematician and aerodynamics expert who formerly worked with ZIPPERMAYER and HOENIG on Pfeil aircraft, torpedoes designed to be released from great heights and torpedoes with luminous underwater trails. Being considered along with HOENIG and ZIPPERMAYER for employment in U. S. by Chemical Corps.
>
> MACHE, Prof. Dr. Heinrich, Pokenvgasse 25, Vienna XIX/117. Professor at Technische Hochschule, Vienna and regular member of Austrian Academy of Science. In October 1945, conducted experiments with coal dust explosives under Soviet orders. Specialist on discharge of electric energy in gases.
>
> ZIPPERMAYR, Prof. Dr. Mario, Lofer Au 3, Zell am See, Austria. Stateless. Chemist. NSDAP member and SD from 1937 to 1945. Headed Zippermayr [blacked out] in coal dust explosives. [blacked out]. See HOENIG and KILLIAN.
>
> BE[ETZ?], Dr.—Halle, Germany. Formerly with Zippermayr Institute engaged in research on methods of transmitting course of enemy bombers to night fighters and on dust explosions.
>
> MELDAU, Dr. Ing—Last reported at Spremberg, Germany. Formerly with Zippermayr Institute engaged in research on coal dust explosives.

Zippermayr and some of the other scientists were extensively interrogated after the war, and some were taken to work for the United States, Russia, or other countries.

Zippermayr's Austrian group was part of a much larger wartime program to develop, test, and mass-produce fuel-air explosives (pp. 544–545).

There were several reports of successful tests of fuel-air explosives during the war. Some archival documents even mentioned fuel-air explosives actually being used on the Eastern front during the war. See pp. 546–555, 2615–2623, 4396–4397.

By the end of the war, at least 7000 workers had mass-produced 5-ton fuel-air explosive bombs and stockpiled them (pp. 556–557). There were also stockpiles of fuel-air explosives in an assortment of smaller sizes. Those stockpiled bombs were probably taken by Allied countries after the war.

Much more historical research on this topic could be quite enlightening.

August 16, 1943

PERSONAL AND CONFIDENTIAL
BY SPECIAL MESSENGER

Major General George V. Strong
Assistant Chief of Staff
G-2, War Department
Washington, D. C.

Dear General Strong:

Information has been received through a confidential source that a German newspaper representative in Spain who had recently come to that country from Germany has stated that Germany has a new weapon. It is a huge liquid air bomb which is to be carried in special aircraft directed by radio rays. The bomb is supposed to be able to destroy everything within a radius of five hundred meters.

It is reported that it is the intention of the German High Command to use this new weapon against the south of England to prepare for an invasion. The German newspaper representative reportedly stated that this weapon cannot be counterbalanced by the Allies, who could not use it against Germany even though they knew all of its secrets of operation because they had no nearby base necessary for its operation. It is reported that the German bases in the north of France are close enough to England to permit its use against England.

I thought this information would be of interest to you as possibly bearing on the DSM Project.

Sincerely yours,

John Edgar Hoover
Director

within 72 Hours.

1. A German medical officer P/W has been interrogated as to his knowledge of compressed air shell.

2. In June 1944 the informant was present at an important medical conference in Berlin which was attended by most of the high-ranking Nazi officers. At this meeting the question of bacteriological warfare was discussed, but the idea was discarded as being impractical. The discussion finally resolved itself around a deadly "compressed air shell" containing a "Green ring" gas. Compressed air shell less the gas filling were said to have been used against the Russians in the Caucasian Kuban sector, but their use was discontinued when the Russians threatened to retaliate with CW. The conference was dismissed when the medical staff strongly opposed the use of this new gas-compressed air shell on the ground that it would endanger the civilian population.

3. The P/W stated that he was present at a field demonstration where 88 mm compressed air-gas shell were employed. The shell was said to have been double-walled with two fuzes in the sides, and marked with a green band around three fourths of the ogive.

4. In this demonstration shell were fired into groups of live animals with devastating effect. The animals were killed immediately through rupture of the internal organs. Externally, the animals were not affected. A safety range of about 1,800 yards was maintained during the trials.

5. This new shell was reported at that time to be in mass production and ready for employment in February 1945. The code word initiating its use was to be "Scharnhorst".

18 April 1945

INTERROGATION OF PW (OFFICER) WITH KNOWLEDGE OF COMPRESSED AIR SHELLS.

1. PERSONALITY: CLAUS, DETLLEV, VIERTH, 1st Lt. 5th Group, V Medical Corps Berlin. Age: 24. Lenght of service: 4 years. This PW was captured when he gave himself up to troops of the 35th Infantry Division in vic BURGSTALL. he had only one year of private medical practice before being ordered into the German Medical Corps. His medical training was extensive and had been taken at Heidelberg, Munich and Hamburg. He has traveled extensively. Since his capture he has busied himself with the medical care of other German PW's. This man stated that at one time he was slated to become a member of a secret service group controlled by the Gestapo but that a trace of Jewish blood existing somewhere along the line of his ancestry prevented this assignment. He claims that he is not a Partei member and he appears to hold a grudge against the Partei. This attitude may account for his eagerness to impart information. In fact, the man implied that such was the case.

The informant, interrogated on 17 April 1945 at the 35th Infantry Division CP, is an intelligent and well educated person. His organization, the V Medical Corps Berlin, ranks very high in German military circles. He is a very willing informant- perhaps a bit too willing- in that he offered his services as a 'stoolpigeon'. He accused the Americans of being very lax in their interrogation procedure and stated that many civilians and PW's were sure to have knowledge of the V weapons and other information of value concerning the German Army. The informant's extreme desire to impart information and his offer of his services as a 'stoolpigeon' is a bit unusual and may only be an effor on this part to curry favor for himself. The man has considerable ego, although he cannot be considered to be conceited. This informant showed not the slightest sign of nervousness during the interrogation. He seemed sincere and his calm and assured recital of facts gave the impression that the man must have some past performances upon which to base hisstory. In view of past stories concerning the compressed air shell, the informant's information is of such a nature that it warrants being fitted into the intelligence picture.

2. PW's STORY

a. Medical conference: The informant stated that in June of 1944 he was notified to attend a medical conference to be held at the KAISERHOF (Ministry of Propaganda in BERLIN. This meeting was called by the General Staff of the German Army and was attended by practically all of the more improtant Nazi officers including General Meyer and General Guderian the tank expert. The informant stated that he was invited to attend this meeting because he was more or less well known to the German medical clique in that he had performed a few favorably considered medical experiments. The conference lasted for three days and its purpose was to bring under medical discussion the possibility of putting a sudden and victorious end to the war through the use of newly developed chemical weapons. The medical staff was to consider and report upon the effects upon the human body of these weapons. Bacteriological warfare eas discussed and the idea discarded as being impractical. Final discussion was centered upon the 'compressed air shell' which was being improved upon by the

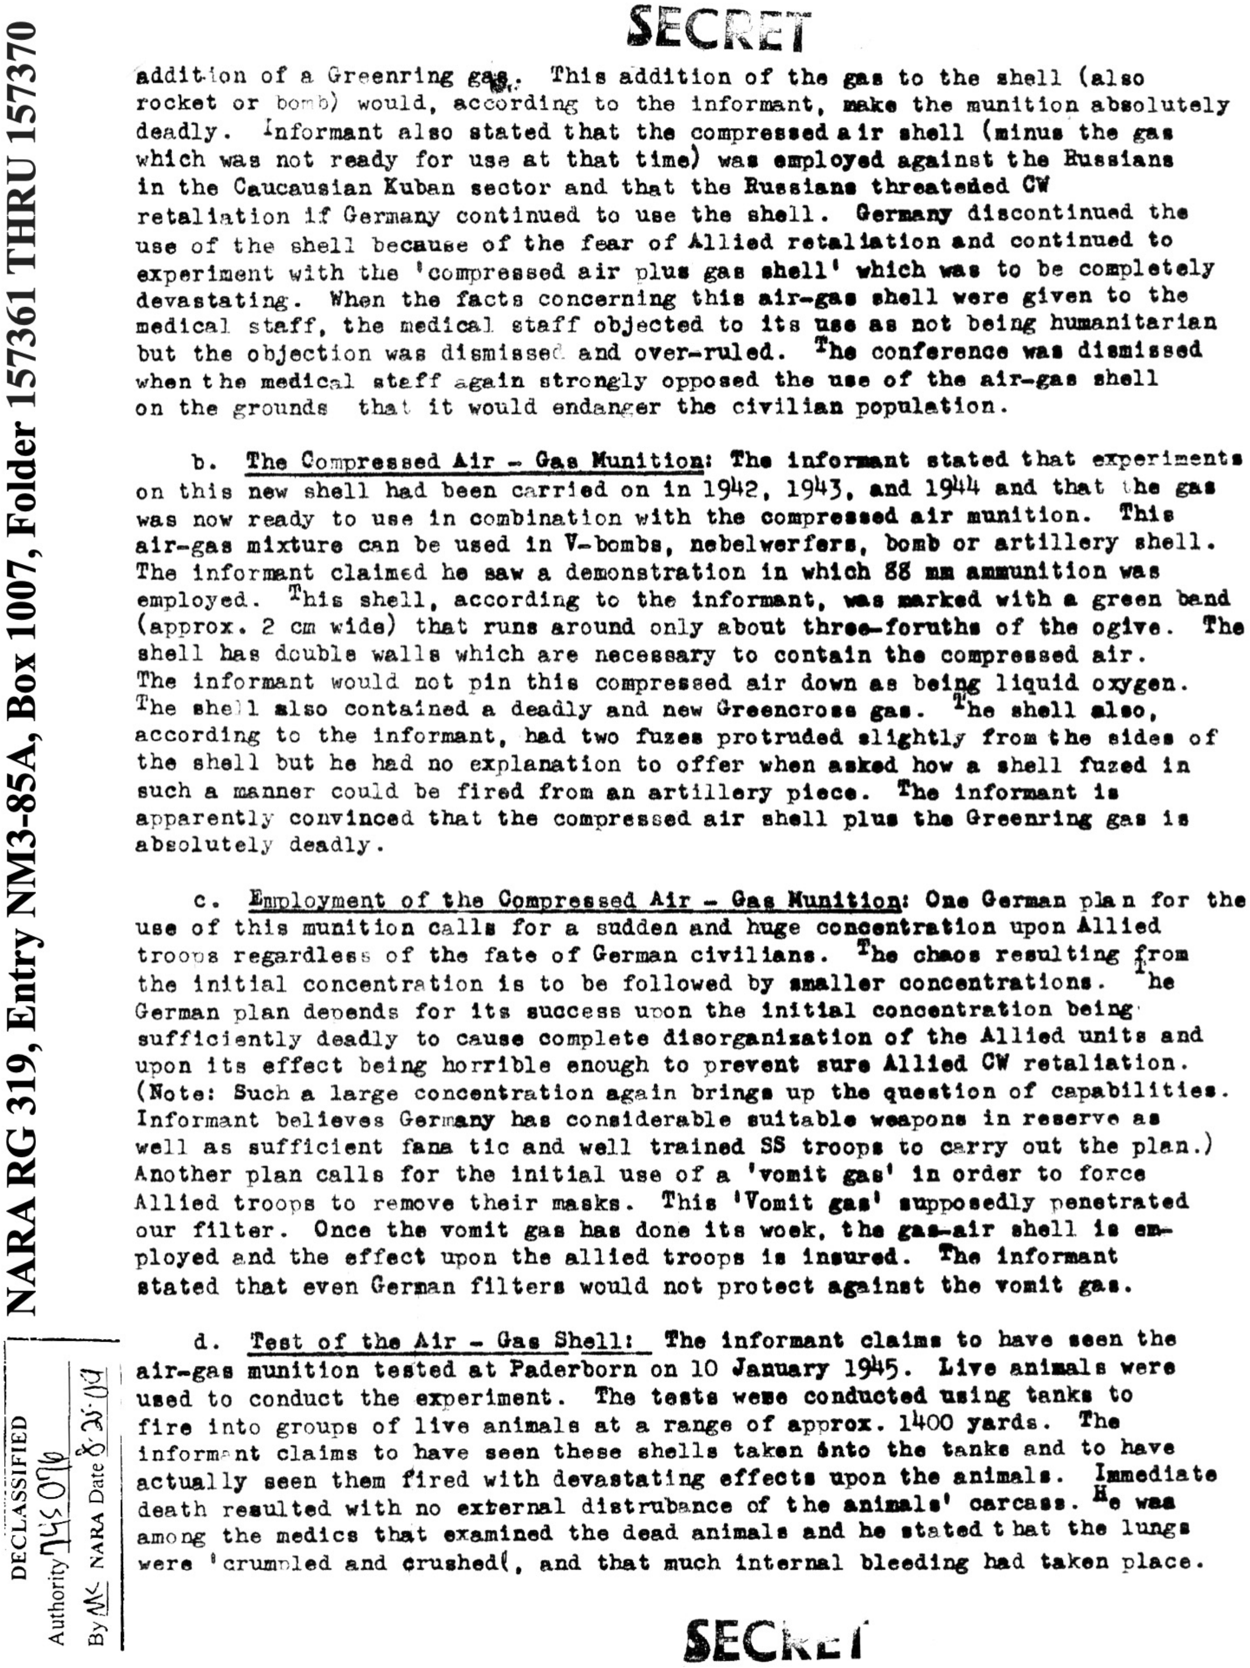
Figure 3.81: A reported test of a fuel-air explosive (or possibly a chemical agent) [NARA RG 319, Entry NM3-85A, Box 1007, Folder 157361 THRU 157370].



SECRET

addition of a Greenring gas. This addition of the gas to the shell (also rocket or bomb) would, according to the informant, make the munition absolutely deadly. Informant also stated that the compressed air shell (minus the gas which was not ready for use at that time) was employed against the Russians in the Caucausian Kuban sector and that the Russians threatened CW retaliation if Germany continued to use the shell. Germany discontinued the use of the shell because of the fear of Allied retaliation and continued to experiment with the 'compressed air plus gas shell' which was to be completely devastating. When the facts concerning this air-gas shell were given to the medical staff, the medical staff objected to its use as not being humanitarian but the objection was dismissed and over-ruled. The conference was dismissed when the medical staff again strongly opposed the use of the air-gas shell on the grounds that it would endanger the civilian population.

b. The Compressed Air - Gas Munition: The informant stated that experiments on this new shell had been carried on in 1942, 1943, and 1944 and that the gas was now ready to use in combination with the compressed air munition. This air-gas mixture can be used in V-bombs, nebelwerfers, bomb or artillery shell. The informant claimed he saw a demonstration in which 88 mm ammunition was employed. This shell, according to the informant, was marked with a green band (approx. 2 cm wide) that runs around only about three-foruths of the ogive. The shell has double walls which are necessary to contain the compressed air. The informant would not pin this compressed air down as being liquid oxygen. The shell also contained a deadly and new Greencross gas. The shell also, according to the informant, had two fuzes protruded slightly from the sides of the shell but he had no explanation to offer when asked how a shell fuzed in such a manner could be fired from an artillery piece. The informant is apparently convinced that the compressed air shell plus the Greenring gas is absolutely deadly.

c. Employment of the Compressed Air - Gas Munition: One German plan for the use of this munition calls for a sudden and huge concentration upon Allied troops regardless of the fate of German civilians. The chaos resulting from the initial concentration is to be followed by smaller concentrations. The German plan depends for its success upon the initial concentration being sufficiently deadly to cause complete disorganisation of the Allied units and upon its effect being horrible enough to prevent sure Allied CW retaliation. (Note: Such a large concentration again brings up the question of capabilities. Informant believes Germany has considerable suitable weapons in reserve as well as sufficient fanatic and well trained SS troops to carry out the plan.) Another plan calls for the initial use of a 'vomit gas' in order to force Allied troops to remove their masks. This 'Vomit gas' supposedly penetrated our filter. Once the vomit gas has done its woek, the gas-air shell is employed and the effect upon the allied troops is insured. The informant stated that even German filters would not protect against the vomit gas.

d. Test of the Air - Gas Shell: The informant claims to have seen the air-gas munition tested at Paderborn on 10 January 1945. Live animals were used to conduct the experiment. The tests wese conducted using tanks to fire into groups of live animals at a range of approx. 1400 yards. The informant claims to have seen these shells taken onto the tanks and to have actually seen them fired with devastating effects upon the animals. Immediate death resulted with no external distrubance of the animals' carcass. He was among the medics that examined the dead animals and he stated that the lungs were 'crumpled and crushed', and that much internal bleeding had taken place.

SECRET

internal organs had also assumed a dirty 'powder-burned' color. Among other conclusions drawn at this test was the fact that the German troops must not be closer to the bursting shell than 1800 yards in order to prevent injury to the troops. When asked if this range included a safety factor, the informant replied that it did or else a 1400 yard range would not have been employed during the test.

e. Compressed air-gas shell Conference in Sudatenland (Joachimstal): The informant claims that he was present for a time at a meeting of the type formerly held in Berlin. This meeting was held about eight weeks ago and again the German medical clique and topnotch Nazi officers were in attendance. The purpose of this meeting was to announce the perfection of the air-gas shell and to discuss its tactical employment. The shell was announced as being perfected and in mass production (informant did not know where) and ready to use. Once again medical objections were voted down. Himmler, high Nazi officials and Gestapo members were in favor of its use and were in favor of an all out 'sink or swim(attempt. If the attempt failed, Germany would go down along with the Nazi regime. Informant stated that Army generals at this meeting for the most part refused to commit themselves. Other Army generals protested against its use as a sure way to bring about Allied chemical warfare. The word 'Scharnhorst', when given to troops is supposedly the code signal that will bring about the use of the air-gas shell.

3. CONCLUSION: Information gained from the informant appears to be a bit vague and confused in regard to certain points, but some of his statements seem fairly reliable and evidently have some measure of foundation. In view of some repors of the use of compressed air shells on the Russian front, the man's story is worthy of some consideration. The informant has been taken to the main Ninth Army PWE and has been tagged for interrogation by higher headquarters.

10. Gas Courses (Continued)

Reduced Gas Discipline

PW claims that gas discipline in his unit was more emphasized in 1944 than in 1945. He has had no gas drill this year. In 1944 unit had one gas drill and weekly gas lectures, which have now been discontinued.

(Source: Florian KLAUSER 4 Coy 48 Regt 12 VG Div captured 7 March vic IMMENDORF)

11. Gas Shells

PW states that SS Pz Div DAS REICH always carries some gas ammo. 10.5 and 15 cm Arty shells containing gas resemble ordinary ammo except for a green, yellow, or blue stripe painted on the nose. Shells are packed in brown wooden boxes (3 shells to a box) with a colored stripe on the cover.

PW saw gas filled 8 cm mortar shells on the E front, Dec 41 - Jan 42. Shells resembled ordinary ammo except for a white stripe, and were packed in grey boxes, 3 to a box. Boxes had a carrying handle. A white stripe was on the box cover.

(Source: U/Scharführer Karl GAJDA SS Regt DER FÜHRER captured 1 March vic MÜNCHEN-GLADBACH)

PW saw 200 kg gas bombs in BARANOWICZE (Poland), July 4. Nose of bombs were marked with yellow, blue, or green stripes.

(Source: O/Gefr Jakob KLEEFISCH 834 Pi Ausb Bn captured 11 March vic LINZ)

Test Firing

Gas shells are test-fired on Übungsplatz RAUBKAMMER vic MUNSTERLAGER. This locality was chosen because it is a safe distance from ammo factory, MUNSTERLAGER, which would have been endangered by detonation of the 30 cm rocket projectors.

(Source: Obst SICKERMANN OC 55 Werfer Regt)

12. Pressluft Ammo

PW saw ammo depot of 19th Army (15 Feb) E of OFFINGEN. The depot covers an area of 1½ - 2 square km N and S of rd OFFINGEN - HASLACH, with the center at GSGS 4416/X2/015332. Only tk, rocket projector, and special ammo was stored there.

He saw 28 cm Pressluft (Stuka zu Fuss) rocket projector ammo marked with white letters "PR(S)". 500 rounds were stored in 3 piles. There was also 28 cm "BRAND ÖL" rocket projector ammo, and 28 cm HE rocket projector ammo. Piles of shells were 500 m apart, according to PW.

12. Pressluft Ammo (Continued)

PW states that Pressluft shells (Stuka zu Fuss) exhaust the oxygen of the air. 3 - 6 shells will destroy everything within a radius of 2 km. PW further claims that it has been used on the Alsace front.

(Source: Gefr Hans KOHREN HQ 63 Army Corps captured 7 March. PW did not seem reliable and appeared to suffer from battle shock.)

13. Radium and Liquid Air Torpedoes

PW was civilian technical expert on high tension electrical systems. He reported weekly at Base Construction Depot, 20 Goslarschestr, HILDESHEIM. He overheard a discussion, middle Jan, on the safest place to store radium and liquid air rocket propelled torpedoes. All the mine shafts in HILS GEBIRGE were reviewed. the asphalt works at ESCHERSHAUSEN was most often mentioned. It is known as GUSTAV ADOLPH STOLLEN (GSGS 4416/P4/361710)

(Source: Martin BINDERNAGEL, arrested URDINGEN? 5 March)

14. On HITLER's Orders

Boxes with the inscription "Nur auf Befehl des Führers zu öffnen" were observed at various locations:

4 - 5 truck loads were observed in HAMBURG - BLANKENSEE, 3 or 4 Feb 45. Boxes were seen in several unidentified places in Germany, 20 Feb. A RR box-car marked with the inscription was seen in JUNKERATH (Eifel), Dec 44.

5-10 bombs marked with the inscription were seen at airport in GARDERMOEN (Norway), Summer 43. Boxes were seen in AVIGNON (France) Jan - Feb 43.

Rocket projector ammo bearing the inscription was seen on E front, 1943. (PW thinks it was filled with Pressluft.) Boxes were seen on E front 1942 by several PWs. It was rumored in one case that contents were gas ammo.

Boxes were grey, black or unpainted, appr 125 x 80 x 40 cm. Inscriptions were seen in black, white, yellow, and red letters, 10 - 15 cm high.

(Source: O/Gefr Otto DOMICK 9 Para Regt captured 4 March vic DURSCHAFEN and 7 others).

To be Opened in "D Falle"

In ODENDORF (nr EUSKIRCHEN), Dec 44, PW saw wooden boxes 130 x 80 x 30 - 35cm, closed with tin bands. Boxes were marked in black letters (10 cm high) "Im 'D' Falle zu öffnen". PW states they were delivered to V-2 sites in area and were later moved to other sites in the Westerwald.

13. Fantasia: German Secret Weapons

Preamble. The following stories are from sources of doubtful reliability and may well be pure products of the imagination. However, in view of the striking similarity between them, they are printed for what they are worth.

First Story

Around 15 Sept 44, CP of 1127 Gren Regt 559 Inf Div was in REINANGE at GSGS 4416/U1/912797. It was a warm, sunny day, with a few scattered clouds and no wind. At about 1600 PW was standing near the church in REINANGE and observed a formation of Allied aircraft pass, flying from SW to NE, low enough to be recognized as four-motored planes. He counted up to 30 planes. They were flying in close formation.

While PW watched them pass by, he saw what he believed to be a small fighter plane (grey color, no identification marks) climb and approach the Allied formation from an easterly direction. PW states that the "fighter plane" was flying at an abnormally high speed and that it penetrated into the midst of the formation apparently without being fired at. Suddenly there appeared, where the "fighter plane" had been before, a red ball of fire, somewhat larger than the plane itself. A split second later, the ball of fire turned into a rapidly expanding red circle (parallel to the ground). This circle was bluish-red at its edge, and as its diameter increased, the interior of the circle became an empty space. As the circle enveloped the planes, they seemed to just disappear. In a matter of seconds the entire formation of Allied planes had disappeared, and the sky was just as it had been before.

PW discussed the incident with several others who had witnessed it, including a Hptm of 1559 Arty Regt. This officer (who was subsequently killed) told him that the "fighter plane" in question was a wooden miniature plane with a speed of over 1000 km per hour and which was operated by remote control. The name of the plane is KOMET. The Hptm told him that he had lived near an airfield where such planes were tested and that he had recognized it at once.

(Source: Werner LUTMER, Uffz. HQ 1127 Gren Regt)

HITLER's Plans. About 10 Oct 44, the CP of 1127 Gren Regt was visited by the 1st general staff officer (I-a?) of XIII SS Corps (an Oberstlt, name unknown). PW talked for about 10 to 15 minutes to this officer's driver, a Rottenfuehrer, who told him the following:

He, the Rottenfuehrer, had overheard a conversation between the general staff officer and HITLER and HIMMLER, who had visited the XIII SS Corps HQ a few days before. During the conversation he had overheard HITLER say that "the new secret weapon" would not be employed until a 24 hour mastery of the air and sea could be guaranteed. HIMMLER is supposed to have added that another prerequisite was a temperature of 10 degrees below 0.

13. Fantasia: German Secret Weapons (Continued)

Second Story

On 6 Jan 44, between 1300 and 1400 hrs, PW saw a formation of four-motored American Liberators flying over STETTIN. He heard a noise like that of a V-2 taking off and saw a large red ball ascending rapidly toward the formation. It appeared to grow as it rose. There was a loud explosion and he saw broken parts of planes falling.

PW comments that there were three divisions(?) of Flak in action at the time (3 x 72 pieces), but when he returned to PEENEMUENDE he was told by a friend who worked in the officers' club that this had been the first attempt with a new secret weapon and that 47 planes were brought down by the single shot. Another friend in Flak Regt 11, STETTIN, told PW that the Flak had fired anti-personnel charges that day instead of usual Flak ammunition. When PW asked why, he was told that the ammunition was left over from AFRICA and had to be used up. PW's own comment (see also PW INTELLIGENCE BULLETIN 1/13 Item 17) is that it makes more noise and might be used to hide the noise of the secret weapon.

(g) Liquid air bomb

As the research on the atomic bomb under Graf von Ardenne and others was not proceeding as rapidly as had been hoped in 1944, it was decided to proceed with the development of a liquid air bomb. Experiments using ordinary powdered coal were not at all successful, but extremely good results were obtained from a mixture consisting of 60% finely powdered dry brown coal and 40%

5.

liquid air. The technical man responsible for this work was Dr. Zippelmeier. The first trial was made on the Döberitz grounds near Berlin using a charge of about 8 kg of powder in a thin tin plate container. The liquid air was poured on to the powder, and the two were mixed together with a long wooden stirrer. Kreutzfeld did this himself, and was present at the ensuing test. In an area of radius 500 to 600 metres trees etc. were all completely destroyed. Thereafter the explosion started to rise and only the tops of the trees were affected, although the intensive explosion covered an area 2 km. in radius. Zippelmeier then had the idea that a better effect might be obtained if the powder was spread out in the form of a cloud before the explosion. Trials were made with a paper container impregnated with some waxy substance. A metal cylinder was attached to the lower end of this container and hit the ground first, dispersing the powder. After a short time interval of the order of 1/4 second a small charge in the metal cylinder exploded and ignited the dark funnel shaped dust - liquid air cloud. The bombs had to be filled immediately prior to the departure of the aircraft. Bombs with charges of 25 and 50 kg. of powder were dropped on the Starbergersee, and photographs of the explosion were taken. Standartenführer Klumm kept a photograph of the result and showed it to Brandt (Himmler's personal adviser). The intensive explosion covered an area 4 to 4.5 km. radius, and the explosion was still felt on a radius 12.5 km. When the bomb was dropped on an airfield, much destruction was caused 12 km. away, and all the trees on a hillside 5 to 6 km. away were flat. On a radius of 12.5 km. only the tops of the trees were destroyed.

A Dr. Hahnenkamp was also concerned in this work with Dr. Zippelmeier, and both scientists were working for the R.L.M. in the laboratories of a research institute near Vienna. About the end of September 1944 Zippelmeier was moved to the Horn Gyroscopic compass factory in Plauen, Vogtland (Saxony), but was probably evacuated before the Russians occupied the area. The materials of the explosive were made by the specialists of the Nobel company.

Figure 3.88: Reported tests of fuel-air explosives [BIOS 142, pp. 4–5]. The tests sound real although the blast radii (reported secondhand and from memory) seem exaggerated for the amounts of explosives and dispersal methods described. The “waxy substance” coating the container was probably to keep the coal dust from sticking to the container.

SECRET

Figure 3.90: By the end of the war, at least 7000 workers had mass-produced 5-ton fuel-air explosive bombs and stockpiled them [NARA RG 331, Entry UD-18A, Box 157, Folder 319.1-2 Reports—Evacuation of Targets & Target Addresses].

3.4.3 Shaped Explosive Charges

Similarly, German-speaking scientists led the development of shaped (or hollow) explosive charges, which concentrate the force of an explosion in a particular direction—for example in the forward direction to penetrate tank armor upon impact (Fig. 3.91), or radially inward in an implosion bomb to compress nuclear fuel (Sections D.8–D.9).[9]

Franz von Baader (German states, 1765–1841, Fig. 3.92) designed and utilized shaped charges for mining.

Gustav Bloem (German?, 18??–19??, Fig. 3.92) invented metal-lined shaped charges as detonator caps.

Carl Julius Cranz (German, 1858–1945, Fig. 3.92) worked on many aspects of ballistics and supported Franz Rudolf Thomanek and others in developing militarily useful shaped charges.

Rolf Engel (German, 1912–1993, Fig. 3.92) was an expert on rockets, explosives, shaped charges, and implosion designs. He worked on secretive weapons projects for the German military during World War II and for the French military after the war.

Ernst Richard Escales (German, 1863–1924, Fig. 3.92) published handbooks and journals about a wide variety of explosives and explosive techniques, including shaped charges.

Max von Förster (German, 1845–1905, Fig. 3.92) designed, tested, and published descriptions of shaped explosive charges.

Hellmuth von Huttern (German?, 19??–19??, Fig. 3.93) worked with Franz Rudolf Thomanek in developing the first prototypes for military shaped charge weapons.

Heinrich Langweiler (German?, 19??–19??, Fig. 3.93) led the team that developed the Faustpatrone and Panzerfaust anti-tank weapons [BIOS 99; BIOS 100]. See also p. 2131.

Hans Mohaupt (Swiss, 1915–2001, Fig. 3.93) brought the concept of shaped explosive charges to the United States, leading to the design of the bazooka.

Egon Neumann (German, 18??–19??, Fig. 3.93) developed sophisticated shaped charge explosives in 1910 and helped to publicize the general concept [George Brown 1998, p. 166; Walters and Zukas 1989, pp. 12–13].

Hubert Schardin (German, 1902–1965, Fig. 3.93) worked for the Luftwaffe as an expert on the design and experimental measurement of shaped explosive charges and implosion bombs [Krehl 2009, pp. 1160–1162; Nagel 2012a, p. 149 ff.]. After the war, he worked for the French military.

Erich Schumann (German, 1898–1985, Fig. 3.93) ran a Heereswaffenamt (Army Ordnance Office) program to design and conduct experimental measurements of shaped explosive charges and implosion bombs [Karlsch 2005; Nagel 2012a].

---

[9] George Brown 1998; DOD 1953; DOW 1945a; Field 2017; Karlsch 2005; Kennedy 1990; Krehl 2009; Mrazek 1970; Nagel 2012a; Simon 1947a; Walters and Zukas 1989; BIOS 99; BIOS 100.

Alfred Stettbacher (Swiss, 1888–1961, Fig. 3.94) designed and tested shaped charges.

Franz Rudolf Thomanek (Austrian, 1913–1990, Fig. 3.94) began designing and developing hollow-charge antitank weapons in 1932 and worked on them until 1945.

Walter Trinks (German, 1910–1995, Fig. 3.94) worked closely with Erich Schumann as part of the Heereswaffenamt (Army Ordnance Office) program to design and conduct experimental measurements of shaped explosive charges and implosion bombs [Karlsch 2005; Nagel 2012a].

The chemist Simon Field [Field 2017, pp. 131–132, 136] emphasized the contributions of many of the above scientists to the development of shaped explosive charges:

> In 1792 the twenty-six-year-old German Catholic philospher, theologist, and mining engineer Franz Xaver von Baader came up with a way of saving gunpowder in mines. The idea was to make a conical of mushroom-shaped hollow in the front of the gunpowder charge. His reasoning was not recorded, and it is not clear what effect it had, if any, but it was used in Norway and later in the mines of the Harz Mountains in Germany[...]
>
> Things were a little different ninety-one years later, in 1883. The chief company engineer of the nitrocellulose factor of Wolff and Co. in Walsrode, Germany, was a man named Max von Förster. Von Förster tested a hypothesis "to give the detonating gases of guncotton a certain direction aiming toward the target" through a series of experiments with hollowed-out charges. "Estimated on the whole, it appears that the effect of the hollow cartridge of the same size and less weight is superior to the full one of more weight." [...]
>
> In 1883 Gustav Bloem patented a metal detonator cap with a hollow in it, to get a "concentration of the effect of the explosion in an axial direction." This was the first lined cavity shaped charge.
>
> [...] Dr. Franz Rudolph Thomanek, on February 4, 1938, discovered the importance of the metal lining. [...] Between then and 1943, Thomanek experimented with different hollow shapes and different liner thicknesses, including tapering the thickness.
>
> In Zurich in 1937 a Swiss engineer, Dr. Henry Hans Mohaupt, also came up with a metal-lined hollow cavity shaped charge, and tried to get the British government to pay him for the expense of developing it. [...]
>
> Mohaupt brought his idea to the United States on October 18, 1940. First developed as a rifle grenade, the idea morphed into a rocket-propelled munition with a shaped charge armor-piercing warhead that became known as the "bazooka" [...]

A small group of German soldiers successfully used two innovations, troop gliders (p. 1689) and shaped explosive charges, to land at and penetrate through the thick reinforced concrete walls of Fort Eben-Emael in Belgium in May 1940 [Mrazek 1970].

For more information on the use of shaped charges and implosion for German nuclear weapons during World War II, see Section D.8.

Zündung eines Sprenggeschosses, dessen Hohlraum-Sprengladung vorn eine vorzugsweise kegelförmige Metallauskleidung aufweist

Patentiert im Gebiet der Bundesrepublik Deutschland vom 9. November 1940 an
Patentanmeldung bekanntgemacht am 9. September 1954
Patenterteilung bekanntgemacht am 12. Juli 1956
Die Priorität der Anmeldung in Frankreich vom 9. November 1939 ist in Anspruch genommen

Die Erfindung bezieht sich auf die Zündung eines Sprenggeschosses, bei dem in der Hohlraum-Sprengladung mindestens eine vorzugsweise kegelförmige Auskleidung angeordnet ist, deren Spitze dem Geschoßboden und deren Basis einem Hohlraum im Kopf des Geschosses zugekehrt ist.

Es ist bekannt, daß Sprengkörper, die mit einem gegen den zu sprengenden Gegenstand, z. B. eine Panzerplatte, gerichteten Hohlraum versehen sind, ein größeres Durchschlagsvermögen erzielen als ein volles Sprenggeschoß von gleichen äußeren Abmessungen. Diese Steigerung der Durchschlagskraft ist unter dem Namen Neumanneffekt bekannt. Die hohlen Sprengkörper werden in Bergwerken und Steinbrüchen viel verwendet, denn man erzielt damit eine beträchtliche Sprengstoffersparnis.

Bei einer früher vorgeschlagenen Anwendung des Neumanneffektes auf Geschosse hat das Geschoß einen dünnwandigen Spitzbogenkopf, der sich beim Aufschlag breit drücken soll. Die Sprengladung enthält vorn einen kegelförmigen Hohlraum, der mit einer kegeligen Metallauskleidung versehen ist, um eine Verlagerung des Sprengstoffes in den Hohlraum beim Abschuß zu verhindern. Man nahm an, daß sich beim Aufschlag nach Zertrümmerung des dünnwandigen Geschoßkopfes der Neumanneffekt in gleicher Weise aus-

Sprengladungskörper für panzerbrechende Geschosse

Patentiert im Deutschen Reich vom 10. September 1940 an
Patenterteilung bekanntgemacht am 4. Oktober 1956

Es sind panzerbrechende Geschosse bekannt, bei denen die Sprengladung einen kugelförmigen, kegelförmigen oder anderen Hohlraum am vorderen Ende hat. Bei einem bekannten derartigen Geschoß ist auch der Hohlraum mit einer Auskleidung versehen zu dem Zweck, die Sprengmasse vor Feuchtigkeit und mechanischen Einwirkungen zu schützen. Die Sprengladungen selbst bestehen aus brisanten bzw. hochbrisanten Sprengstoffen, wie aromatischen Nitrokörpern, z. B. Trinitrotoluol, Pikrinsäure usw., oder aus Hexogen, Tetranitropentaerythrit, Nitroglyzerin oder auch aus Mischungen derartiger Sprengstoffe. Sie können aber auch aus Sprengstoffen auf Ammonsalpeterbasis bestehen. Da die Körper durch Pressen der Sprengstoffe hergestellt wurden, bestand die Gefahr, daß beim Abschuß des Geschosses der Sprengkörperhohlraum eingedrückt wird. Um dies zu verhindern, soll nach dem bekannten Vorschlag eine Auskleidung angebracht werden, die unter Berücksichtigung der Abschußgeschwindigkeit bemessen wird.

Der besonderen Gestaltung des Hohlkörpers und der Auskleidung ist bisher keine größere Bedeutung beigelegt worden. Die Erfindung beruht demgegenüber auf der Feststellung, daß die panzerbrechende Wirkung von Ge-

3.4.4 Radio Control and Electric Timers for Explosives

In addition to developing explosives, German-speaking creators invented precise electrical means of detonating the explosives, including radio control and electric timers.

Ferdinand Schneider (German, 1866–1955) invented radio-controlled mines in 1904 and patented them in many countries, directly inspiring subsequent copies and implementations. See Fig. 3.95. Schneider also created many other electrical inventions, including radio systems, radio-synchronized clocks, depth charges, audiovisual equipment, and wind turbines.

As shown in Fig. 3.96, Herbert Rühlemann (German, 1902–19??) invented time-delay electric bomb fuses in the 1920s. Ernst Marquard (German, 1897–1980) helped to further develop them during World War II.

Bombs equipped with such time-delay fuses can be set to detonate hours, days, or even longer after they are dropped. Because people in the targeted region do not know what times the fuses are programmed for, they do not know if it is safe to begin clearing and repairing the damage from the attack. Thus time-delay bombs can cause much more chaos and institutional paralysis than bombs that detonate immediately upon impact, especially when bombs with many different time settings are dropped at once.

Both Rühlemann and Marquard aided ordnance development in the United States after the war.

No. 850,972. PATENTED APR. 23, 1907.

F. SCHNEIDER.

WIRELESS RECEIVING APPARATUS FOR EXPLODING MINES.

APPLICATION FILED JAN. 3, 1906.

UNITED STATES PATENT OFFICE.

FERDINAND SCHNEIDER, OF LANGENFELD, GERMANY.

WIRELESS RECEIVING APPARATUS FOR EXPLODING MINES.

No. 850,972. Specification of Letters Patent. Patented April 23, 1907.

Application filed January 3, 1906. Serial No. 294,490.

To all whom it may concern:

Be it known that I, FERDINAND SCHNEIDER, a citizen of Germany, residing at Langenfeld, Rheinland, Prussia, have invented a new and useful Wireless Receiving Apparatus for Exploding Mines; and I do hereby declare the following to be a full, clear, and exact description of the same.

My invention relates to the receiving-wires of the receiving apparatus.

In Figures 1 and 2 of the annexed drawings the new receiving apparatus is diagrammatically illustrated by way of example. Fig. 3 shows the electric exploding apparatus in a larger scale.

Referring to a submarine mine, as shown in Fig. 1 of the annexed drawings, an electric exploding apparatus *c* is inserted into the floating-mine casing *b* for the purpose of firing the charge of the mine by means of electric waves. The mine *j* is anchored to the bottom *n* of the sea by means of the anchor *l*, so that it is situated below the water-level *a*. The receiving-wires *d* and *e*, consisting of cables with india-rubber sheaths, are connected to the electrodes *o p* of the electric exploding apparatus and are made tight at the place where they are led into the mine-casing. The ends *h* and *i* of the receiving-cables are supported by the floats *f* and *g* and are so formed that they extend into the air in the form of tufts. The positions of the floats *f g* may be specially secured by means of anchors *k* and *m*.

For land-mines, Fig. 2, the receiving-wires *e′ d′* are also made of india-rubber-insulated cable and are placed under the earth's surface *a′* and lead to the casing *b′* of the mine and exploding apparatus. The ends of the receiving-wires extend out of the soil as terminal capacities *h′ i′* in the form of tufts.

This receiving arrangement for electric waves has the advantage that the terminal capacities thereof are not conspicuous, which is desirable for purposes of military engineering.

The electric exploding apparatus *c*, which is also disclosed in a separate patent application, Serial No. 281,548, filed October 5, 1905, and entitled "Improvement in apparatus for exploding mines by means of electric waves," is more particularly shown in Fig. 3. The two metal strips 3 and 4 are so fastened to the board 2 that the coherer-gap is formed at 1. Both these strips 3 and 4 are bent to form an angle at 5 and 6, respectively.

A circular recess is formed in the board 2, into which fits one of the well-known alarm-clocks. The clock is fastened to the board by means of angle-pieces 24 23, and the dial and the hands of the clock are visible from the back of the board 2. When the alarm is running down, the hammer 22 strikes against both the angle-bends 5 and 6.

The knob 18 serves for setting the time at which the explosion is to take place and the knob 17 for setting the hands of the clock. The key 15 is for winding up the works of the clock, and the key 14 serves for winding up the alarm. The movement of the key 14 is restricted to ninety degrees by means of stops 20 21. At the back of the clock is secured a vulcanite strip 11, to which the contact-springs 10 12 are fitted. The upper contact-spring 12 carries the contact-pin 13, which is pressed down to form contact by the part 19 of key 14. The contact-spring 12 is conductively connected with the coherer-electrode 4 by wire 16 and contact-screw 26. The spring 10 is conductively connected by the wire 9 with the positive pole of the battery 8, while the negative pole is conductively connected by the wire 7 and contact-screw 25 with the coherer-electrode 3. The electrodes 3 and 4 are connected to the receiving-wires *d e*.

The apparatus works as follows: The clock is wound up and the hands set to the proper time, and then the time at which the explosion is to take place is also set by means of the knob 18. The key 14 is now turned through an angle of ninety degrees from left to right until it comes into contact with the stop 21, thus winding up the spring of the alarm, and the contact of the springs 12 and 10 is opened, so that the battery 8 is now switched off. The person laying the mine then shakes the igniting coherer-powder onto the division 1, so that it covers the surface between the angles 5 6. This coherer-powder, which is disclosed in a separate patent application, Serial No. 281,549, dated October 5, 1905, and entitled "An explosive coherer-powder," consists of minute and very thin metallic leaves mixed or aggregated with an explosive. It has this property, that it is non-conductive, so that even high potentials may be employed without passing through. If, however, this coherer-powder is submitted to the action of electric waves, this resistance is partially overcome. The current flows through and heats the mass to incandescence, so that the explosive powder mixed with it is ignited, thus igniting the explosive piled up or arranged near it.

As described above, the battery-contact 12 10 is opened on winding up the alarm, so that any electric waves resulting at the same time are no source of danger to the layer of the mine, as although the latter waves render the powder conductive nevertheless, the circuit being opened, no action can result. After a certain time the spring of the alarm runs down, the hammer 22 begins to work, and by striking against the angles 5 6 thoroughly shakes up the powder, so that it is completely decohered when the part 19 of the key 14, turning from right to left, presses down the contact-pin and connects the local battery with the coherer. This decohering of the powder before the closing of the local circuit is important, because it prevents that when the powder should be decohered by waves arising during the laying of the mine it is ignited at once by merely closing the local circuit. After closing the local circuit the coherer is ignited by electric waves and can therefore be exploded from sparking stations situated at a distance.

Having thus described my invention, what I claim as such, and desire to secure by Letters Patent, is—

1. Receiving apparatus for exploding submarine and land mines adapted to be exploded by the aid of electric waves, comprising a mine-chamber, an exploding device arranged in said chamber and sensitive to electric waves, and long horizontal receiving-wires connected with said exploding apparatus.

2. Receiving apparatus for explosive submarine and land mines adapted to be exploded with the aid of electric waves, comprising a mine-chamber, an exploding device arranged in said chamber and sensitive to electric waves, and long receiving-wires connected with said exploding apparatus the said receiving-wires being insulated with the exception of their ends.

3. Receiving apparatus for explosive submarine and land mines adapted to be exploded with the aid of electric waves, comprising a mine-chamber, an exploding device arranged in said chamber and sensitive to electric waves, and long insulated receiving-wires connected with said exploding apparatus and arranged in such a manner that only the free ends thereof extend into the atmosphere, the other portions of said cables being situated below the surface of the water or earth.

4. Receiving apparatus for explosive submarine and land mines adapted to be exploded with the aid of electric waves, comprising a mine-chamber, an exploding device arranged in said chamber and sensitive to electric waves and long insulated receiving-wires connected with said exploding apparatus said wires being situated below the surface of the water or earth with the exception of the free tuft-like ends which extend into the atmosphere.

5. Receiving apparatus for explosive submarine mines adapted to be exploded with the aid of electric waves, comprising a mine-chamber, an exploding device arranged in said chamber and sensitive to electric waves, and long insulated receiving-wires connected with said exploding apparatus and arranged in such a manner that only the free ends thereof extend into the atmosphere, said ends being supported by floats, the other portions of said cables being situated below the surface of the water.

6. Receiving apparatus for explosive submarine mines adapted to be exploded with the aid of electric waves, comprising a mine-chamber, an exploding device arranged in said chamber and sensitive to electric waves, and long insulated receiving-wires connected with said exploding apparatus and arranged in such a manner that only the free ends thereof extend into the atmosphere, said ends being supported by anchored floats, the other portions of said cables being situated below the surface of the water.

In testimony whereof I have signed my name to this specification in the presence of two witnesses.

FERDINAND SCHNEIDER.

In presence of—
BESSIE F. DUNLAP,
LOUIS VANDORN.

3.5 Chemical Warfare Agents and Pesticides

German-speaking scientists dominated the development of chemical warfare agents and pesticides, including:[10]

3.5.1. First-generation chemical weapons

3.5.2. Insecticides

3.5.3. G-series nerve agents

3.5.4. V-series nerve agents

3.5.5. Other chemical weapons

Figure 3.97 illustrates the chemical structures of some major chemical warfare agents and pesticides.

Figures 3.98–3.110 show some of the German-speaking scientists who were involved in developing and testing chemical warfare agents and pesticides.

3.5.1 First-Generation Chemical Weapons

Several compounds became famous or infamous after their first use in World War I (Fig. 3.97). They were developed by German-speaking scientists, but then later copied and used by other countries.

The cyanide-containing Prussian blue pigment was developed in the German-speaking world around 1700. Hydrogen cyanide gas derived from the Prussian blue pigment was called Prussic acid. It was deployed to some extent on WWI battlefields, but was also used as an insecticide. In World War II, it was called Zyklon B and used in the gas chambers of the Holocaust, yet even long after the wars, it was still used for government executions in the United States.

Chlorine gas, two chlorine atoms bonded together, was used on World War I battlefields, and is caustic to lungs, eyes, and other sensitive tissues with which it comes into contact.

In phosgene gas, the two chlorine atoms were coupled to a carbon atom and an oxygen atom, making the molecule more readily absorbed by tissues and hence even more toxic.

In mustard agent, the two chlorine atoms were linked to a hydrocarbon chain. This hydrocarbon chain gave mustard agent an oily feel, made it persist on surfaces for long periods of time instead of rapidly dispersing like a gas, and allowed it to penetrate through skin so that it could attack even people wearing gas masks.

---

[10] Friedrich et al. 2017; Gellermann 1986; Gröhler 1989; Hager 2008; Harris and Paxman 2002; Hein Hofmann 2008; Kaszeta 2020; Pfingsten 2003; Stoltzenberg 1994, 2005; Szöllösi-Janze 2015; Tucker 2006; Zecha 2000; BIOS 110; BIOS 542; BIOS 714; BIOS 760; BIOS 761; BIOS 782; CIOS ER 33; CIOS II-1; CIOS IX-4; CIOS XI-12; CIOS XXI-4; CIOS XXIV-19; CIOS XXVI-49; CIOS XXVII-34; CIOS XXVIII-59; CIOS XXX-19; CIOS XXXI-86; CIOS XXXII-13.

The U.S. chemical weapons expert Jonathan Tucker described how Fritz Haber (German, 1868–1934) and other German scientists developed the first generation of chemical warfare agents [Tucker 2006, pp. 10–12, 18–19]:

> Because Germany possessed the world's most advanced chemical industry, it enjoyed an inherent advantage in this type of warfare. [...]
>
> The individual who became responsible for developing chemical weapons for the German War Office was Professor Fritz Haber, a brilliant young chemist and ardent Prussian nationalist who directed the Kaiser Wilhelm Institute for Physical Chemistry in Berlin. [...]
>
> In late 1914, Haber had the idea of loading artillery shells with chlorine, which the German chemical industry produced in large quantities for the production of dyestuffs. When a shortage of artillery shells ruled out this method of delivery, he proposed instead that chlorine be released directly from pressurized gas cylinders, allowing the wind to carry the poisonous cloud over the enemy's trenches. [...]
>
> In mid-January [1915], Haber ordered the chemist Otto Hahn and several other colleagues to help prepare the chlorine attack. [...] The German chemists helped to organize a special unit for gas warfare called Pioneer Regiment 36. [...]
>
> In December 1915, the Germans fired shells containing phosgene, a gas used in the dye industry that was eighteen times more toxic than chlorine. [...]
>
> In an effort to circumvent the Allied use of protective masks and respirators, Haber and his colleagues developed a new chemical warfare agent that attacked the skin as well as the lungs. Called "mustard" because of its sharp, garlicky odor, it was an oily liquid that was readily absorbed through the skin, giving rise after several hours to severe chemical burns and blisters. In July 1917, once again at Ypres, the Germans began firing mustard-filled shells containing an explosive burster charge that shattered the liquid agent into a fine mist that was colorless or light yellow. Like phosgene, the effects of mustard were insidious: symptoms developed only after a delay of three to twenty-four hours (with a mean of ten to twelve hours), so that troops often did not realize that they had been exposed to the agent until it was too late.
>
> [...] Mustard soon became the most dreaded of chemical weapons and was dubbed "the king of the war gases." Not only was it highly persistent, clinging to clothing and equipment and contaminating the battlefield for days or even weeks, but its ability to penetrate the skin forced troops to augment their respirators with cumbersome oilskin capes, goggles, and leather or rubber garments. This protective gear could be worn only for short periods, however, because it caused heat stress and seriously impaired fighting efficiency.

Fritz Haber won the 1918 Nobel Prize in Chemistry for unrelated work to chemically synthesize ammonia on an industrial scale (p. 447).

During World War I, Fritz Wilhelm Lommel (German, 1875–1968) and Georg Wilhelm Steinkopf (German, 1879–1949) developed a chemical method for the large-scale synthesis of mustard agent. Ever since then, mustard agent has commonly been known in the German-speaking world as LOST, combining the first two letters of their last names.

3.5.2 Insecticides

The German-speaking world also produced the most important early insecticides, which had a worldwide impact and became the prototypes for improved insecticides. Dichloro-diphenyl-trichloromethylmethane (DDT, Fig. 3.97), with five chlorines coupled to two benzene rings, was first produced in 1874 by Othmar Zeidler (Austrian, 1850–1911). Paul Hermann Müller (Swiss, 1899–1965) discovered DDT's insecticidal properties in 1939. DDT was rapidly transferred from the German-speaking world to many other countries [Brooks 1974, pp. 7–17] and was widely used to curtail insect-borne diseases in the 1940s–1960s. Müller won the Nobel Prize in Physiology or Medicine in 1948 for DDT, drawing the praise of Professor G. Fischer, a member of the Staff of Professors of the Royal Caroline Institute [https://www.nobelprize.org/prizes/medicine/1948/ceremony-speech/]:

> The story of DDT illustrates the often wondrous ways of science when a major discovery has been made. A scientist, working with flies and Colorado beetles discovers a substance that proves itself effective in the battle against the most serious diseases in the world. Many there are who will say he was lucky, and so he was. Without a reasonable slice of luck hardly any discoveries whatever would be made. But the results are not simply based on luck. The discovery of DDT was made in the course of industrious and certainly sometimes monotonous labour; the real scientist is he who possesses the capacity to understand, interpret and evaluate the meaning of what at first sight may seem to be an unimportant discovery.
>
> Dr. Paul Müller. I have tried to give a brief survey of the historical development of DDT. Your discovery of the strong contact insecticidal action of dichloro-diphenyl-trichloromethylmethane is of the greatest importance in the field of medicine. Thanks to you, preventive medicine is now able to fight many diseases carried by insects on a way totally different from that employed heretofore. Your discovery furthermore has, throughout the world, stimulated successful research into newer insecticides.

DDT was phased out starting in the 1960s due to concerns about environmental side effects, as most famously articulated in Rachel Carson's 1962 book, *Silent Spring*. However, it was replaced by other insecticides that came from the German-speaking world.

Scientists in the German-speaking world developed a number of chemical derivatives of DDT that appeared (and in some cases still appear) to be safer. One was dichlorodiphenyldichloroethane (DDD), also known a ME-1700. Others were difluorodiphenyltrichloroethane (DFDT, also known as Lauseto) and monofluorodiphenyltrichloroethane (MFDT), which as of 2019 were still being considered as attractive and relatively safe insecticides [Zhu et al. 2019].

Hermann Staudinger (German, 1881–1965) and Leopold Ružička (Austro-Hungarian/Croatian, studied in Germany and worked in Switzerland, 1887–1976) identified pyrethroid insecticide molecules in 1924, and pyrethroid insecticides have been widely used from the 1960s onward as a safer replacement for DDT. Staudinger won the Nobel Prize in Chemistry in 1953 for his work on polymers (p. 474), and Ružička won the Nobel Prize in Chemistry in 1939 for his work on hormones (p. 353).

Other early insecticides had an even more profound impact. Organophosphate compounds, containing both a phosphorus atom and several carbons, were developed as insecticides by Paul Gerhard Schrader (German, 1903–1990). Parathion (Fig. 3.97) was one of the earliest and best-known examples, and numerous variations such as malathion were subsequently produced and used to the present day. Yet because some of the early organophosphate insecticides had some toxicity to humans as well as insects, they proved to be the key to developing more modern chemical warfare agents—rapidly acting nerve agents.

3.5.3 G-Series Nerve Agents

Scientists in the Third Reich produced and tested a wide variety of organophosphate nerve agents, and created several especially potent ones (which were given postwar codenames beginning with G for German): tabun (GA), sarin (GB), soman (GD), ethylsarin (GE), cyclosarin (GF), and isopentylsarin (GH). (The code name GC was not used, to avoid confusion with the U.S. code name for phosgene, CG [Tucker 2006, p. 105]. GG was likely skipped because of the double letters.) See Fig. 3.97. Schrader created all of the agents just listed, except for soman which was developed by Richard Kuhn (Austrian, 1900–1967). After their initial discovery and testing, the agents were mass-produced by I.G. Farben at several industrial plants led by the chemist Otto Ambros (German, 1901–1990). These G-series nerve agents were exclusively possessed by the Third Reich and were stockpiled but never used, due to fear that Allied nations would retaliate with much cruder but still effective first-generation chemical weapons such as mustard agent (pp. 2632–2651).

Jonathan Tucker described the sophistication of nerve agent research, development, and production during the Third Reich [Tucker 2006, pp. 42, 45, 47–48, 50–51]:

> Code-named "Hochwerk," it would eventually cover an area 1.5 kilometers long by 700 meters wide. [...]
>
> Because of shortages of key equipment and manpower, it took two years and an expenditure of 120 million reichsmarks to complete the Hochwerk plant at Dyhernfurth, which the Anorgana company headed by Ambros began to operate in the spring of 1942. The sprawling production complex included buildings for manufacturing basic chemical ingredients, intermediates, and final products; numerous warehouses and storage tanks; a bombproof bunker that could hold 1,000 tons of bulk agent; filling lines for loading Tabun into artillery shells and aerial bombs; a well-equipped medical clinic with a staff of trained physicians; and barracks for the plant workers. To reduce exposure to air raids, the main production facility was built partially underground and camouflaged with trees planted on the roof.
>
> Because of Tabun's extreme toxicity, the design of the Hochwerk facility included special features to protect the plant workers against exposure. Each kettle was housed in an enclosed operating chamber formed of two spaced glass walls. Between the glass walls, a ventilation system produced greater than atmospheric pressure, so that the flow of air was always toward the reaction kettle. Inside the operating chamber, the air above the kettle was continuously changed by means of a separate ventilating duct, creating negative pressure. This pressure differential meant that the air contaminated with Tabun fumes was retained inside the operating chamber. All pipes used to transfer solutions containing Tabun were double-walled, and their outer surfaces were sprayed frequently with a weak solution of ammonia and water to neutralize minor leaks. After each production run, the kettles were decontaminated with steam and ammonia.
>
> No technicians were allowed to enter the operating chambers while the production of Tabun was under way. Instead, the operators opened and closed valves with long-handled mechanical levers that penetrated the double glass walls through rubber-sealed gaskets. [...]

> Although the standard Germany Army gas mask protected against breathing contaminate air, Tabun could also be absorbed through the skin. For this reason, all mechanics who entered the sealed production chambers to perform repairs and maintenance wore not only a respirator but a protective suit, cap, boots, and gloves, encapsulating the entire body. The suit consisted of two layers of rubber separated by a layer of cloth, making it cumbersome and unbearably hot in summer. Despite these precautions, about a dozen fatal accidents occurred during the two and a half years of Tabun production, most of them affecting mechanics performing overhauls of the plant. In one incident, seven pipe fitters were struck in the face by a pressurized stream of liquid Tabun that forced itself between their respirators and rubberized suits. [...]
>
> All seven victims were given intramuscular injections of atropine and a new drug called Sympotal, but five did not respond to the antidotes and died. [...]
>
> Dyhernfurth had its own munition-loading facility, which was built underground and equipped with ventilation shafts. Steel artillery shells and bomb casings were manufactured in a separate building and place on conveyor belts that transported them to the filling plant. Liquid Tabun pumped from underground storage tanks was loaded into empty 105 mm and 150 mm artillery shells, 250-kilogram aerial bombs, and artillery rockets. [...] To compensate for Tabun's lack of volatility, the bombs contained a central "burster" tube filled with a high explosive that, detonated on impact with the ground, would shatter the liquid agent into a mist of tiny droplets, poisoning enemy soldiers through inhalation and skin contact.
>
> Once an aerial bomb had been loaded with Tabun, the filling port was closed with a plug that incorporated a tightening pin. Using a wrench, a technician applied seating pressure to the pin, causing it to shear off and leave the plug in a sealed position, flush with the surface of the weapon. The sealing plug and adjacent surface were then coated with a slow-drying pink lacquer that would turn a deep carmine if Tabun lead through the plug. Near the base of the bomb or shell, workers painted three green rings around the munition to indicate its contents, along with stenciled numbers providing the date of manufacture and a code letter indicating the ratio of Tabun to chlorobenzene. [...]
>
> The forced laborers were assigned the most menial, backbreaking, and dangerous tasks at the Tabun plant, including construction, maintenance, and loading munitions with the liquid agent. On the filling line, they wore protective clothing similar to a deep-sea diving suit, with a helmetlike mask covering the entire head and a hose providing a supply of fresh air. [...]

While Gerhard Schrader synthesized tabun, sarin, and hundreds of other possible nerve agents and pesticides, Jonathan Tucker described the role that Richard Kuhn also played in the program [Tucker 2006, pp. 54, 62–63]:

> In early 1943, Colonel Schmidt of the Army Ordnance Office asked Professor Richard Kuhn, the director of the Institute of Chemistry at the Kaiser Wilhelm Institute for Medical Research in Heidelberg, to analyze the effects of nerve agents on the central and peripheral nervous systems. [...]

> Based on these insights, Kuhn's research team developed a standardized assay that measured the ability of nerve agents to inhibit purified cholinesterase enzymes in the test tube. Over the next two years, they used this assay to screen a variety of candidate nerve agents, some of their own invention and others synthesized by the German Army chemists at Spandau Citadel. [...]
>
> [D]uring the spring of 1944, Richard Kuhn, working at the Kaiser Wilhelm Institute in Heidelberg, made a striking discovery. He was continuing his research for the German Army by screening a wide variety of organophosphorus compounds—some of which he had synthesized himself—for the ability to inhibit cholinesterase. Because of the Nazi obsession with secrecy, his research was "compartmented": he was not put into contact with other scientists in the nerve agent field and was completely unaware of Schrader's work.
>
> When Kuhn replaced the isopropyl alcohol used to make Sarin with a more complex alcohol known as pinacolyl, the resulting substance (which he called Compound 25075) had a camphorlike odor and was roughly twice as potent as Sarin in inhibiting cholinesterase. The War Office code-named this new compound "Soman," and Kuhn synthesized small amounts in the laboratory.
>
> Toxicological testing of Soman in animals by Dr. Gross at IG Elberfeld revealed that the new agent was twice as toxic as Sarin by inhalation, readily penetrated into the skin, and passed rapidly from the bloodstream into the brain, enhancing its lethal effects. Even more striking, Soman inactivated cholinesterase irreversibly within two minutes, severely limiting the effectiveness of atropine as an antidote. Over the next several months, Kuhn and his colleagues tested about fifty analogues of Sarin and Soman for their ability to inhibit cholinesterase in his test-tube system. The most promising compounds were then tested on dogs and apes. [...]

Unlike the view in conventional history books, both Axis and Allied forces very nearly used chemical weapons in World War II. Germany stockpiled and very seriously considered using its chemical weapons (both the newer ones like nerve agents and the older ones like mustard agent) against Allied targets, especially to halt Russian advances on the Eastern Front. The United States and United Kingdom stockpiled and very seriously considered using their own copies of the chemical weapons that Germany had invented in the previous war (mustard and phosgene) with the explicit goal of killing millions of civilians in German cities. The threats by both sides to use chemical weapons played an enormously important role in how and why the war was waged as it actually was. For more information, see pp. 2632–2651.

The G-series nerve agents and information on how to produce them were removed from Germany at the end of the war, and G-series agents have been mass-produced by a wide range of nations ever since. For example, the postwar U.S./U.K. chemical warfare program was directly copied from the wartime German program, making extensive use of German scientists, information, and materials [Tucker 2006, p. 116]:

> In addition to Schieber, EUCOM hired about thirty German chemical warfare experts, some of whom were later transferred to Edgewood Arsenal to continue their work on

> American soil. [...] Several of the German chemical weapons specialists recruited by Porton Down later moved to the United States, where they were granted U.S. citizenship and prominent positions.

Similarly, the postwar Soviet chemical warfare program was also directly copied from the wartime German program [Tucker 2006, pp. 106–107, 145]:

> In September 1946, with the aid of captured German scientists, Soviet engineers and pipe fitters had systematically dismantled the Tabun and Sarin plants at Dyhernfurth, which the Red Army had seized as war booty, and shipped the production equipment to Stalingrad. [...]
>
> To assist in rebuilding the nerve agent production lines, the Soviets brought to Stalingrad about a dozen German chemists and process engineers from Dyhernfurth who had been captured by the Red Army. The most senior of the German scientists were Dr. von Bock, the former production manager. Soon after his arrival, he was ordered to write a detailed technical report on Tabun production and was questioned at length about the metal corrosion problems associated with the manufacture of Sarin.
>
> The Sarin plant at Stalingrad started out as a copy of the one at Dyhernfurth, but for reasons of national pride [Zaharovich] Soborovsky and [Boris] Libman tried to improve on the German production process. In so doing, they ran into serious technical problems that resulted in lengthy delays. [...] Although the development had begun in 1948, it was not until 1959—more than a decade later—that Chemical Works No. 91 was churning out large amounts of Sarin with a satisfactory level of purity and stability.

3.5.4 V-Series Nerve Agents

A significant innovation in nerve agents first became publicly known after the war. Although G-series agents were relatively small molecules that dispersed fairly rapidly, if they were coupled to an oily hydrocarbon chain, they could persist on surfaces for long periods of time and also readily penetrate through human skin. These improved nerve agents became known as the V-series (for venomous); VX was the favorite in the United States and United Kingdom, and the similarly acting VR was the favorite in the Soviet Union (Fig. 3.97). Officially, the invention of this category of nerve agents was credited to postwar researchers not from the German-speaking world. In 1952, Ranajit Ghosh and J. F. Newman at the UK Imperial Chemical Industries (ICI) Plant Protection Laboratory produced a potent V-series agent, Amiton, that had been intended as an insecticide. Almost simultaneously, Lars-Erik Tammelin of the Swedish Institute of Chemical Defense produced similar compounds that came to be known as Tammelin esters.

In fact, V-series agents appear to have been invented, produced, and tested in Germany during World War II.

The chemical approach of coupling a toxic gas molecule to an oily hydrocarbon chain—in order to make the agent persist on surfaces and penetrate through human skin—is exactly the same strategy that German chemists used during World War I to upgrade chlorine gas to mustard agent (Fig. 3.97).

German chemists would be expected to consider the same approach to upgrade nerve agents during World War II. Making the most toxic German chemical agents persist much longer in the environment, so that they could be used to contaminate areas and block a Soviet advance (see p. 2633 for such plans), would be a very obvious and very high-priority goal.

Indeed, in 1945 Gerhard Schrader gave U.K. and U.S. officials detailed information on many hundreds of nerve agents that he had developed and tested during the war [BIOS 714; see Fig. 3.112 and Section A.4]. Schrader's report included a wide variety of V-series agents, composed of G-series agents coupled to an oily hydrocarbon chain. Furthermore, many of Schrader's agents possessed the same molecular features as VX and VR, such as using a nitrogen atom to attach two branches of hydrocarbons to the toxic part of the molecule. After the war, Schrader, Ernst Schegk, and Hanshelmut Schlör of Bayer in Leverkusen (part of I.G. Farben during the war) filed patents on linking an oily hydrocarbon chain to a toxic organophosphate structure, although postwar restrictions both delayed public acknowledgement of that work and compelled them to focus on insecticide applications instead of chemical warfare applications; see Fig. 3.113 and Section A.4.

In the United States (and likely in other countries as well), German experts such as Friedrich Wilhelm Hoffmann (1910–1967) were employed after the war to mass produce V-series agents. Hoffmann was also deeply involved in the postwar U.S. development (or perhaps the postwar transfer/recapitulation of wartime German work) of the Agent Orange defoliant, dioxin, various other toxins, attempts to harness LSD, and other chemical agents.[11]

It is quite possible that Richard Kuhn or others also developed V-series agents in Germany during the war. Much more archival research is needed to clarify the history of the development and dissemination of knowledge about V-series agents.

THE DEVELOPMENT OF NEW INSECTICIDES AND CHEMICAL WARFARE AGENTS

Preface

In August - September, 1945, an investigating team interviewed, amongst others at Kransberg-Dustbin, Dr. Gerhard Schrader, a research chemist, late of the I.G. Works Elberfeld. A brief account was obtained of the history of his important series of researches on organic fluorine and phosphorus compounds, embracing the discovery of the nerve gases Tabun and Sarin, and of a number of potent insecticides. This account is included in B.I.O.S. Final Report No.44, Item No.8.

At the conclusion of the interrogation, the team requested Dr. Schrader to prepare a fuller account of this work, including preparative details, his ideas on the relationship between chemical constitution and toxicity towards insects and warm-blooded animals, and his suggestions for future work. In response to this request several voluminous reports, in part overlapping have been received. Dr. Schrader has been handicapped in writing these by the destruction or inaccessibility of his records and notes, so that there are certain gaps, especially in the insecticidal data and the preparative methods. Despite this it has been possible after translation to piece together a coherent account of his work.

Fortunately several files have come to light containing what appear to be the results of sorting tests for toxic effect against aphids of a large number of the substances listed in Schraders papers. These results have been inserted in the Appendices. Some compounds are mentioned several times in these files and occasionally different figures are quoted for the insecticidal activity of the same compound. Where this is so, the higher activity has been included in this report.

Details of the sorting test used by the entomologist working with Schrader have not been found.

The very fact that details are nowhere given is however evidence that it was a standard routine test and for this reason the results can be accepted as giving a good indication of comparative toxicity.

Verfahren zur Herstellung von neutralen Estern der Thiophosphorsäure

Patentiert im Gebiet der Bundesrepublik Deutschland vom 8. Mai 1949 an
Patenterteilung bekanntgemacht am 6. September 1951

Es ist bekannt, daß sich Salze der Thiophosphorsäureester folgender Konstitution:

$(RO)_2P(O)S-Me$

mit Alkylhalogeniden zu den entsprechenden neutralen Estern umsetzen lassen. In vielen Fällen führt dieses Verfahren aber nur dann zum Ziel, wenn als Salze die der Schwermetalle, wie Blei oder Silber, und als Alkylhalogenide die Jodide gewählt werden. Es wurde nun gefunden, daß sich die neutralen Ester der Thiophosphorsäure leicht herstellen lassen, wenn beliebige Alkylrhodanide, die im Alkylrest in beliebiger Weise substituiert sein können, mit den technisch leicht herstellbaren Alkalisalzen der Dialkylphosphite zur Umsetzung gebracht werden. Unter Abspaltung von Alkalicyanid bilden sich die gewünschten Ester. Es war nicht vorauszusehen, daß die Reaktion diesen Verlauf nehmen würde. Das Schema der Reaktion ist folgendes:

$$(RO)_2P(O)Na + CNS \cdot R \longrightarrow (RO)_2P(O)-S-R + NaCN.$$

Die Alkylreste R können gleich oder verschieden sein. Es lassen sich nach dem neuen Verfahren Verbindungen herstellen, die sich durch stärkste kontaktinsektizide Wirkungen auszeichnen. An folgenden Beispielen soll das Wesen der neuen Reaktion erläutert werden.

Schädlingsbekämpfungsmittel

Patentiert im Gebiet der Bundesrepublik Deutschland vom 11. Oktober 1949 an
Patenterteilung bekanntgemacht am 23. August 1951

Es wurde gefunden, daß sich neutrale Ester der Thiolphosphorsäure folgender Zusammensetzung

$(R_1O)(R_2O)P(O)-S-R_3$

(R_1 und R_2 stehen für beliebige Alkylreste, R_3 steht für einen beliebig substituierten Arylrest) hervorragend zur Bekämpfung von saugenden und fressenden Insekten aller Art eignen. Die genannten Ester sind z. B. durch Umsetzung von Dialkoxyphosphorsäurechloriden mit Thiophenolen nach an sich bekanntem Verfahren erhältlich.

Die neuen Ester können als Staub oder, vermischt mit einem Emulgator und Wasser, als Emulsionen zur Anwendung gebracht werden. Folgende Beispiele mögen das Gebiet der Erfindung erläutern:

Beispiele

1. Junge Apfelbäumchen, die von Blattläusen befallen sind, werden mit einer wäßrigen Lösung bespritzt, die 0,005 % folgender Verbindung

(Kp. 1,5 mm/148°)

enthält. Bereits nach 3 Stunden beginnen die Blattläuse abzufallen. Nach 5 bis 6 Stunden sind alle Blattläuse abgetötet.

2. Petrischalen werden mit einem Staub einge-

Verfahren zur Herstellung von Thiopyrophosphorsäureestern

Patentiert im Gebiet der Bundesrepublik Deutschland vom 7. September 1949 an
Patenterteilung bekanntgemacht am 20. September 1951

Es wurde gefunden, daß sich Thiopyrophosphorsäureester folgender Zusammensetzung:

$(R_1O)(R_2O)P(O)-S-P(O)(OR_3)(OR_4)$

(R_1 bis R_4 können gleiche oder verschiedene Alkylreste sein), die bisher noch nicht bekanntgeworden sind, in technisch guter Ausbeute durch Umsetzung von Dialkylphosphiten mit Schwefeldichlorid oder dem durch eine sekundäre Base substituierten Schwefeldichlorid, den Dialkylaminosulfensäurechloriden herstellen lassen. Bei der Umsetzung wird im ersten Falle Salzsäure frei, die zweckmäßig durch Zugabe eines Säurebindemittels, z. B. Pyridin, Dimethylanilin u. a., gebunden werden kann. Im zweiten Fall wird die entstehende Salzsäure durch das gleichzeitige entstehende Dialkylamin gebunden. Die Umsetzung vollzieht sich nach folgenden beispielsweise angeführten Gleichungen:

$$SCl_2 + 2\,(C_2H_5O)_2 \cdot P(O)-H \longrightarrow (C_2H_5O)_2 \cdot P(O)-S-P(O)(OC_2H_5)_2 + 2\,HCl \quad (1)$$

bzw.

$$(CH_3)_2 \cdot N \cdot SCl + 2\,(C_2H_5O)_2 \cdot P(O)-H \longrightarrow (C_2H_5O)_2 \cdot P(O)-S-P(O)(OC_2H_5)_2 + (CH_3)_2NH \cdot HCl. \quad (2)$$

Verfahren zur Herstellung
von insekticid wirksamen
O,O-Dialkyl-S-phenyl-thiono-
thiolphosphorsäureestern

Anmelder:
Farbenfabriken Bayer Aktiengesellschaft,
Leverkusen-Bayerwerk

Dr. Ernst Schegk, Wuppertal-Elberfeld,
und Dr. Gerhard Schrader, Wuppertal-Cronenberg,
sind als Erfinder genannt worden

1

Es wurde gefunden, daß man insekticid wirksame O,O-Dialkyl-S-phenyl-thiono-thiolphosphorsäureester durch Umsetzung von Dialkylthionophosphorsäurechloriden mit substituierten Phenylmercaptanen dadurch herstellen kann, daß als substituierte Phenylmercaptane Nitrophenylmercaptane, die gegebenenfalls im Phenylrest durch Halogen oder Alkylreste weitersubstituiert sind, verwendet werden.

Die neuen Thionothiolphosphate zeichnen sich durch hohe Beständigkeit gegen hydrolytische Einflüsse und durch sehr gute kontaktinsekticide Wirkungen aus. Gegenüber den vergleichbaren Thiolphosphorsäureestern, die z. B. aus der deutschen Patentschrift 817 753 bekannt sind, zeigen die neuen Thiono-thiolphosphorsäureester eine wesentlich geringere Toxizität gegenüber Warmblütern.

Außerdem sind die erfindungsgemäßen Verbindungen auch den aus der deutschen Patentschrift 885 176 her bekannten Verbindungen überlegen, und zwar sowohl hinsichtlich der Toxizität als auch hinsichtlich einer besseren Wirksamkeit. Aus der folgenden Gegenüberstellung sind diese Tatsachen zu ersehen:

Verglichen wurden der erfindungsgemäße Dithiophosphorsäureester

3.5.5 Other Chemical Weapons

German-speaking scientists discovered and developed other categories of chemical weapons too. For example, R. P. Linstead and T. J. Betts, the British and American chairs of the Combined Intelligence Objectives Subcommittee (CIOS), described "N-Stoff" or chlorine trifluoride, a highly corrosive and incendiary German chemical weapon, in a September 1945 report [AFHRA A5186 electronic version pp. 904–1026, Ch. 4, p. 54]:

> A new method was discovered for the manufacture of chlorine trifluoride. The value of this compound is said to lie in its powerful oxidizing properties which causes organic materials to burst into flame immediately on contact. It also has a quality of liberating fluorine which attacks glass and rapidly obscures vision in planes or military vehicles.

Chemical weapons expert Dan Kaszeta provided more background information on N-Stoff/chlorine trifluoride [Kaszeta 2020, p. 39]:

> The Falkenhagen site was already in use for production of chemical warfare materiel unrelated to the nerve agent programme. In 1938, ground had been broken there for a complex to produce Chlorine Trifluoride (ClF_3), which the Army had nicknamed "N-stoff"—literally "substance N". It is a particularly vile substance. A very strong oxidizer, it is both extremely corrosive and poisonous and could be more readily considered to be an incendiary weapon. It burns many different things, even in the absence of oxygen and even ignites glass on contact. It reacts with water, including moisture on the skin. The German military had considered Chlorine Trifluoride as a possible weapon to attack fortifications such as the Maginot Line because it will burn through concrete.

Germany may have actually employed 5-kilogram shells of chlorine trifluoride[12] on the Eastern Front. An English translation of an Allied-intercepted 9 December 1944 Japanese message from Stockholm to Tokyo reported [NARA RG 457, Entry A1-9004, Japanese Army Attaché Messages Translations, SRA 14,200 thru 15,000. SRA 14628–14632. Photos in Pellas 2020, pp. 15–17]:

> [...] It is a fact that in June of 1942 the German Army tried out an utterly new type of weapon against the Russians at a location 150 kilometers southeast of Kursk. Although it was the entire 19th Infantry Regiment of the Russians which was thus attacked, only a few bombs (each round up to 5 kilograms) sufficed to utterly wipe them out to the last man. [...]
>
> The following is according to a statement by Lieutenant-Colonel UE(?K?)I KENJI, advisor to the attaché in Hungary and formerly (?on duty?) in this country, who by chance saw the actual scene immediately after the above took place:
>
> "All the men and the horses (?within the area of?) the explosion of the shells were charred black and even their ammunition had all been detonated."
>
> Moreover, it is a fact that the same type of war material was tried out in the Crimea, too. At that time the Russians claimed that this was poison-gas, and protested that if Germany were ever again to use it, Russia, too, would use poison-gas. [...]

A number of other German chemical agents with incendiary, freezing, neuropharmacological, and other properties were also reported.

---

[12] Or perhaps fuel-air explosive shells or another novel weapon?

3.6 Physical Chemistry

Due to the dominance of creators from the greater German-speaking world both in the field of chemistry and in the field of physics, it is not surprising that they founded and led the area of physical chemistry, the intersection between chemical and physical phenomena.[13] Physical chemistry encompasses many topics such as thermochemistry, electrochemistry, photochemistry, and physical methods for analytical chemistry.

Some important creators in physical chemistry are shown in Figs. 3.114–3.123 and discussed in alphabetical order in Section 3.6.1.

Electrochemical battery and fuel cell technologies are discussed in more detail in Section 3.6.2.

For closely related creators and creations in quantum physics and statistical physics, see Sections 5.4 and 5.5, respectively.

3.6.1 General Physical Chemistry

Hermann Aron (German, 1845–1913) developed an improved lead-acid rechargeable battery in 1880, and it became widely used thereafter. He also developed improved methods of measuring electrical voltage and current [Katzir 2009, 2013].

Svante Arrhenius (1859–1927) was Swedish but studied and worked in Germany and Austria. In fact, throughout most of his education and career, he encountered considerable opposition to his scientific innovations in Sweden, but was given strong support and assistance by creators such as Ludwig Boltzmann, Rudolf Clausius, Friedrich Kohlrausch, Wilhelm Ostwald, and Jacobus van 't Hoff. Arrhenius was one of the founders of the field of physical chemistry and won the Nobel Prize in Chemistry in 1903 for his theoretical insights into electrolytic dissociation. H. R. Törnebladh, President of the Royal Swedish Academy of Sciences, explained the importance of Arrhenius's work [https://www.nobelprize.org/prizes/chemistry/1903/ceremony-speech/]:

> Around 1880 Svante Arrhenius—then studying for a doctorate in science—arrived, as a result of his researches into the movement of electric current through solutions, at a new explanation of the causes of chemical phenomena, i.e. he attributed them to electrical charges contained in the constituents of reacting substances. Electricity was thus introduced as a decisive factor into the theory of chemistry[...]
>
> In the time of Berzelius this notion rested on a qualitative basis only, whereas Arrhenius's theory determined it quantitatively, thus allowing it to be treated mathematically. In his doctor's thesis, twenty years ago, Arrhenius had deduced from this principle all known laws governing chemical changes, but despite this the new theory was very little understood. It so conflicted with current ideas as to disprove them. According to this theory, for instance, common salt, sodium chloride, when dissolved in water splits up to

---

[13] For more information on this area, see especially: Brock 1993; Laurie Brown et al. 1995; Bugge 1955; Coffey 2008; Engels et al. 1989; Farber 1961; Gamow 1966; Ihde 1984; Johnson 1990; Jones 2008; Jungnickel and McCormmach 1986, 2017; Kragh 2002; L'Annunziata 2016; von Meÿenn 1997; Ingo Müller 2007; Neufeldt 2003; Partington 1957, 1964; Teichmann et al. 2008; Weber 1988.

> a varying extent, in other words it is *dissociated* into its constituent parts which are diametrically opposed but charged with electricity, i.e. into *ions of chlorine* and of *sodium*, the only chemically effective substances in a solution of common salt. The theory also claimed that when an acid and a base react upon one another, water is the primary product and salt the secondary, and not reversely, as was then generally believed. Ideas so contrary to those current at that time could not be accepted immediately. A struggle lasting more than ten years and an enormous number of new experiments were required before the new theory was accepted by everyone. During this long battle over Arrhenius's theory of dissociation tremendous advances were made in chemistry and ever closer links were established between chemistry and physics—to the great benefit of both sciences.

Emil Bauer (Swiss, 1873–1944) developed novel fuel cells, such as a fuel cell using molten silver as the electrolyte. Together with Hans Preis, he developed the first fuel cell with a solid electrolyte, in this case one made of paste and metal oxides.

Henri Bernard Beer (Dutch, 1909–1994) invented improved electrodes made of titanium coated with mixed metal oxides containing metals such as rhodium, platinum, iridium, or ruthenium.

Jürgen Otto Besenhard (German, 1944–2006) played a major role in developing lithium batteries. It could be beneficial for historians to conduct much more archival research to investigate just how far back the history of the development of lithium batteries goes, and what contributions various scientists from the greater German-speaking world made during that development process.

Ludwig Boltzmann (Austrian, 1844–1906) developed an extensive framework of statistical physics equations for describing the thermodynamic behavior of large numbers of particles in solids, liquids, or gases [Boltzmann 1964]. As part of that work, he gave a precise mathematical definition of entropy for the second law of thermodynamics. In addition to its importance to physics, Boltzmann's work had enormous implications for chemical equilibria and chemical reactions.

Robert Bunsen (German, 1811–1899) made many important discoveries in physical chemistry. He invented the Bunsen cell battery using carbon electrodes (instead of more expensive platinum electrodes as had been used previously). He studied photochemical reactions, and he employed electrolysis to purify different metals. With Gustav Kirchhoff, he used spectroscopy to analyze and identify chemical elements.

Alexander Classen (German, 1843–1934) made important contributions to electrochemistry, including electrolytic gravimetry and rotating electrodes. The American Council of Learned Societies noted [ACLS 2000, p. 194]:

> First to make thorough study of electrogravimetric analysis (*Quantitative Analyse auf elektrolytischem Weg*, 1881); his innovative methods, which became standard practice, included use of warm solutions, introduction of measuring devices into the circuit, and substitution of storage cells for galvanic cells.

In 1850, Rudolf Clausius (German, 1822–1888) was the first to clearly articulate the second law of thermodynamics, that entropy cannot decrease, or equivalently that heat flows from regions of higher temperature to regions of lower temperature. He also did important work on phase transitions and other aspects of physical chemistry.

Peter Debye (Dutch, 1884–1966) studied and worked in Germany and Switzerland for many years. He developed statistical models of the behavior of molecules, chemical solutions, and crystalline solids. For his work, he won the Nobel Prize in Chemistry in 1936 (p. 914).

Manfred Eigen (German, 1927–2019) developed methods of measuring very fast chemical reactions. He won the Nobel Prize in Chemistry in 1967 for those innovations. Professor H. A. Ölander of the Nobel Committee for Chemistry announced the award [https://www.nobelprize.org/prizes/chemistry/1967/ceremony-speech/]:

> Professor Dr. Manfred Eigen. Although chemists had long been talking of instantaneous reactions, they had no way of determining the actual reaction rates. There were many very important reactions of this type, such as the neutralization of acids with alkalis. Thanks to you, chemists now have a whole range of methods that can be used to follow these rapid processes, so that this large gap in our chemical knowledge has now been filled.

Tibor Erdey-Grúz (Hungarian, 1902–1976) studied the electrochemistry of ionic conductivity, corrosion, and catalysis. Together with Max Volmer, he developed an equation describing the relation between voltage and current in electrolytic solutions.

Richard Ernst (Swiss, 1933–) developed nuclear magnetic resonance (NMR) spectroscopy methods that are useful for studying chemical molecules and biological systems. For that work, he won the Nobel Prize in Chemistry in 1991. Professor Sture Forsén of the Royal Swedish Academy of Sciences praised his research [https://www.nobelprize.org/prizes/chemistry/1991/ceremony-speech/]:

> Professor Ernst,
>
> You have played a leading role in several of the most significant methodological developments that have taken place in the field of NMR spectroscopy over the past two decades; developments that have had a lasting impact on the way modern chemistry is conducted. You have, in an admirable way, combined excellent experimental know-how with extraordinary theoretical insight. In recognition of your services to chemistry, and to natural science as a whole, the Royal Swedish Academy of Sciences has decided to confer upon you this year's Nobel Prize for Chemistry.

Joseph von Fraunhofer (German states, 1787–1826) invented the spectroscope and was the first to use spectroscopy to analyze chemical elements. Robert Bunsen and Gustav Kirchhoff later built upon his work on spectroscopic chemical analysis. Von Fraunhofer also made important innovations in the production of high-quality glass. See pp. 680, 961, and 1260.

In 1885, Carl Gassner (German, 1855–1942) demonstrated and patented the world's first dry batteries, which used zinc, carbon, and a paste electrolyte. See Fig. 3.126.

Heinz Gerischer (German, 1919–1994) began his research on electrochemistry during World War II and continued in that field for the rest of his career, making a number of major discoveries regarding electrode kinetics, electrode reactions, and electrode diagnostics. He also made important contributions to photochemistry.

Michael Grätzel (German, 1944–) invented dye-sensitized photoelectrochemical cells for converting sunlight to electricity more cheaply and efficiently than had previously been possible.

Theodor Grotthuß (German states, 1785–1822) conducted early experiments on electrolysis and developed the first theory of charge transport in electrolytes (now called the Grotthuß mechanism) in 1806. He also developed important early theoretical explanations of photochemical reactions.

Fritz Haber (German, 1868–1934) made tremendously important contributions not only to most other areas of chemistry, but also to physical chemistry, particularly with regard to electrochemistry, combustion, and chemical bond energies [Hager 2008; Stoltzenberg 1994; Szöllösi-Janze 2015]. He won the Nobel Prize in Chemistry in 1918 for his development of industrial-scale ammonia synthesis (p. 447).

Wilhelm Heinrich Heintz (German, 1817–1880) analyzed the physical structure of molecules, including fatty acids, uric acid, amines, and others. He also studied chemical reaction kinetics and the properties of a number of metals.

Frederik Wilhelm Hellesen (Danish but closely tied to the German-speaking research world, 1836–1892) produced dry zinc-carbon batteries in 1887.

Hermann von Helmholtz (German, 1821–1894) made foundational contributions to the thermodynamics of chemical reactions, most notably by defining what came to be known as the Helmholtz free energy. In 1847, he published a more detailed treatment of the first law of thermodynamics, *Über die Erhaltung der Kraft* (*On the Conservation of Energy*), and also studied the thermodynamics of fluids. Von Helmholtz also made major discoveries in biology (pp. 239, 282, 297, 311) and physics (p. 859) [Cahan 2018].

Gerhard Herzberg (German, 1904–1999) made important discoveries regarding molecular structures, molecular spectroscopy, and highly reactive free radical molecules. He won the Nobel Prize in Chemistry in 1971 for his work in those areas. Professor Stig Claesson of the Royal Swedish Academy of Sciences explained the importance of Herzberg's research [https://www.nobelprize.org/prizes/chemistry/1971/ceremony-speech/]:

> Herzberg began as a physicist and his first contributions to molecular spectroscopy were published at the end of the 1920's. In such investigations one measures how molecules absorb light-energy—also outside the visible region—i.e. in the ultraviolet and infrared. Since light-energy is packaged as quanta, these measurements can provide accurate information about energy contents in molecules. From this information their size, shape and other properties can be derived. Such calculations must be based on the description of matter given by quantum mechanics. The development of this subject during the 1920's and 30's is regarded as one of the most exciting periods in the history of physical science. Herzberg's elegant experimental investigations combined with his theoretical insight into their interpretation contributed to the progress of quantum mechanics while being decisive for the rapid development of molecular spectroscopy.
>
> One may now ask why Herzberg—originally a physicist and even famous as an astrophysicist—finally was awarded the Nobel Prize in chemistry.
>
> The explanation is that around 1950 molecular spectroscopy had progressed so far that one could begin to study even complicated systems of great chemical interest. This is brilliantly demonstrated by Herzberg's pioneering investigations of free radicals. Knowledge of their properties is of fundamental importance to our understanding of

> how chemical reactions proceed.
>
> For a chemical reaction to occur the original molecules must in some way break up into fragments which rearrange to form the new molecules. These fragments, or intermediates, are called free radicals.
>
> Free radicals are very difficult to study due to their short life-times—measured in millionths of a second. Herzberg therefore had ample opportunity to repeatedly demonstrate his exceptional experimental skill when the necessary spectroscopic technique was worked out.
>
> Herzberg has so far performed extensive precision determinations of the properties of over thirty free radicals among which are to be found the radicals methyl and methylene—well known from organic chemistry. Among his exciting discoveries may be mentioned that radicals drastically change their shape with increasing energy. For example, methylene is linear in its ground state but bent in states of higher energy. Many of the most important results were only achieved after several years' work and some of the most exciting as late as at the end of the 1960's. One can therefore note that this year's prize is truly an award for contributions of great current interest.

In 1840, Germain Hess (Swiss, 1802–1850) formulated what is now known as Hess's law, a form of the first law of thermodynamics (conservation of energy) applied to a series of chemical reactions. He also studied the thermodynamics of the dissolution of various salts in water.

Jaroslav Heyrovský (Austrian/Czech, 1890–1967) developed polarographic and electroanalytic methods of analyzing chemical samples. For those innovations, he won the Nobel Prize in Chemistry in 1959. The Royal Swedish Academy of Sciences summarized his work [https://www.nobelprize.org/prizes/chemistry/1959/ceremony-speech/]:

> Chemical and electrical phenomena are often associated, as in the case of redox reactions, when electrons are emitted and absorbed. In 1922 Jaroslav Heyrovský discovered a method for analyzing the occurrence and content of various substances in solutions using electrical measurements. The solution is analyzed with two electrodes, one of which is a dropping mercury electrode. At a voltage specific for different substances, redox reactions cause the current to rapidly increase to a level dependent on the concentration of the substance.

Johann Wilhelm Hittorf (German, 1824–1914) conducted very careful electrolytic experiments to measure the mobilities of different ions in solution, the values of which are now called Hittorf ion transport numbers. He was also one of the earliest scientists to experiment with high-voltage tubes and electron beams (p. 862).

Roald Hoffmann (born Roald Safran, Polish, 1937–) made important discoveries regarding the behavior of electrons in chemical bonds, for which he won the Nobel Prize in Chemistry in 1981. The Royal Swedish Academy of Sciences described his research [https://www.nobelprize.org/prizes/chemistry/1981/ceremony-speech/]:

> In chemical reactions, molecules composed of atoms meet and form new compounds. Electrons orbiting around the atoms' nuclei play an important role here. After Kenichi

> Fukui proved that the properties of the electron orbits that most weakly bound to the atom are critical in chemical reactions, Roald Hoffmann went on to further develop these theories from the mid-1960s. Independently of one another, Roald Hoffmann and Kenichi Fukui both demonstrated how the symmetrical properties of electron orbitals explain the course of chemical reactions.

Erich Hückel (German, 1896–1980) developed the Hückel molecular orbital theory to explain double and triple covalent bonds in molecules. He also worked with Peter Debye to create the Debye-Hückel theory of electrolytic solutions. Oxford University's *Biographical Dictionary of Scientists* summarized some of his research accomplishments [Porter 1994, pp. 350–351]:

> Debye and Hückel suggested that strong electrolytes dissociate completely into ions, explaining the deviations from expected behaviour in terms of attraction and repulsion between the ions. In a series of highly mathematical investigations they found formulae for calculating the electrical and thermodynamic properties of electrolytic solutions, principally dilute solutions of strong electrolytes. [...]
>
> In 1930, Hückel began his work on aromaticity, the basis of the chemical behaviour of benzene, pyridine and similar compounds. The benzene molecule is held together by electrons that are delocalized and contribute to one large hexagonal bond above and below the plane of the molecule. This accounts for its planar shape and its ability to preserve its structure through chemical reactions. Hückel developed a mathematical approximation for the evaluation of certain integrals in the calculations concerned with the exact nature of the bonding in benzene.
>
> Later in the 1930s, he extended his research to other chemical systems that appear to possess the same kind of aromatic nature as benzene (although usually to a lower degree). From this study emerged the Hückel rule for monocyclic systems[...]
>
> Hückel also carried out research into unsaturated compounds (those with double or triple bonds) and into the chemistry of free radical compounds (those with a free, non-bonding electron).

In 1899, Ernst Waldemar Jungner (Swedish but closely tied to the German-speaking research world, 1869–1924) created nickel-cadmium, nickel-iron, and silver cadmium rechargeable batteries (Fig. 3.127). He also developed improved fuel cells and electrolytic systems. Nickel-cadmium and other rechargeable batteries were mass-produced and harnessed for a variety of applications in the German-speaking world.

Karl Kellner (Austrian, 1851–1905) developed an industrial electrolytic process for producing chlorine gas and sodium hydroxide, both of which were useful reagents for manufacturing other commercial chemical products.

Gustav Kirchhoff (German, 1824–1887) derived equations to predict the heat of reaction in thermochemistry. Working with Robert Bunsen, he used spectroscopy to analyze and identify chemical elements. Kirchhoff made major discoveries in many areas of chemistry, physics, and engineering (see also pp. 427, 858, 915, 945, and 957).

Friedrich Kohlrausch (German, 1840–1910), the son of Rudolf Kohlrausch (p. 859), was an experimentalist who worked on a wide range of topics in chemistry, physics, and physical chemistry over his career. He developed and used accurate methods of measuring the electrical conductivity of electrolytes, and he also studied the properties of mercury. In addition, he developed experimental techniques and instruments for measuring thermal conductivity, elasticity, magnetic fields, and optical properties.

Walter Kohn (Austrian, 1923–2016) developed new methods to calculate the behavior of electrons in large molecules and in solid materials. For that work, he won the Nobel Prize in Chemistry in 1998, as explained by Professor Björn Roos of the Royal Swedish Academy of Sciences [https://www.nobelprize.org/prizes/chemistry/1998/ceremony-speech/]:

> In two landmark articles from 1964 and 1965, Walter Kohn showed an alternative way in which quantum mechanical equations can be approximated. He showed that there is a one-to-one correspondence between the energy of a quantum mechanical system and its electron density, which is a function of three positional coordinates only and is, therefore, much easier to handle than the complicated wave function, which depend on the positions of all electrons. He also developed a method which made it possible to construct a set of equations, which could be used to determine the energy and electron density. This approach, called density functional theory, has developed during the last ten years into a versatile computational tool with many applications in chemistry. Due to its simplicity, it can be applied to larger molecules than the wave function based methods. Density functional theory has made it possible to study the mechanisms of chemical reactions in enzymes, for example when water is transformed into oxygen in photosynthesis.

Hermann Kolbe (German, 1818–1884) developed methods of using electrolysis with carboxylic acids and fatty acids, now called Kolbe electrolysis. He was also one of the founders of organic chemistry (p. 471).

Karl Kordesch (Austrian, 1922–2011) worked on advanced battery programs in wartime and early postwar Austria, then came to the United States as part of Operation Paperclip. Drawing upon his experience with advanced battery research in Austria, he headed the battery development program at the U.S. Army's Fort Monmouth laboratory, then headed two Union Carbide groups to develop fuel cells and batteries in parallel. He and the other members of his Union Carbide battery group filed the first patents on alkaline (manganese dioxide) dry batteries (Fig. 3.129). He also invented hydrazine-air fuel cells and developed thin carbon electrodes that revolutionized hydrogen-oxygen fuel cells (Fig. 3.130). In view of the great importance that the United States placed on importing Kordesch in Operation Paperclip, putting him in charge of a battery development program for the Army, and placing him in charge simultaneously of two different programs at Union Carbide, it seems highly likely that Kordesch's postwar U.S. projects were based on earlier discoveries by him or others in Austria and Germany. It is difficult to trace that history from the publicly available documentation, but more archival research in this area could be quite enlightening.

Irving Langmuir (American but studied in Germany, 1881–1957) did important work on surface chemistry, the study of chemical reactions that occur at the surface of a liquid or solid. For his discoveries, he won the Nobel Prize in Chemistry in 1932. The Royal Swedish Academy of Sciences described Langmuir's research [https://www.nobelprize.org/prizes/chemistry/1932/langmuir/facts/]:

> Chemical reactions often take place more easily next to surfaces where substances in different phases, such as solids and gases, come in contact. In studies of incandescent

> light bulbs with rarefied hydrogen gas, Irving Langmuir discovered that a layer of hydrogen atoms only one atom thick formed on the inside of the incandescent light bulb. Further studies of oil films and other materials led him in 1917 to a theory postulating that surfaces resemble a chessboard on which every square can be occupied by only one atom or molecule. As a result, atoms or molecules that wind up next to each other can more easily react with one another.

Max Le Blanc (German, 1865–1943) created many innovations in electrochemistry, including the hydrogen electrode for pH measurement, control of voltage during electrolysis to selectively deposit different metals, and improved methods of measuring voltages and currents in solutions.

Johann Josef Loschmidt (Austrian, 1821–1895) studied the physical structures and sizes of molecules. He developed methods to determine the number of gas molecules within a given volume of air. In his honor, that number for standard temperature and pressure is now called the Loschmidt constant, approximately 2.69×10^{25} molecules/m^3 at 0^oC and 1 atmosphere of pressure. Loschmidt also used the then-new second law of thermodynamics in theoretical explanations of the behavior of chemical compounds and solutions.

Julius von Mayer (German, 1814–1878) expressed the first law of thermodynamics, the law of conservation of energy (including heat energy and work), in 1841. He was also the first to find equations for the specific heat of an ideal gas, or the relationship between the amount of heat energy absorbed by a substance and the corresponding temperature rise for that substance. He was one of the first to attempt a scientific analysis of photosynthesis, and he created Mayer's reagent for detecting alkaloids.

Karl Friedrich Mohr (German, 1806–1879) developed improved methods of volumetric analysis and chemical titration. In an 1837 journal article, he became the first known scientist to state the first law of thermodynamics (conservation of energy) [Mohr 1837]:

> Ausser den bekannten 54 chemischen Elementen gibt es in der Natur der Dinge nur noch ein Agens, und dieses heisst Kraft; es kann unter den passenden Verhältnissen als Bewegung, chemische Affinität, Cohäsion, Elektricität, Licht, Wärme und Magnetismus hervortreten, und aus jeder dieser Erscheinungsarten können alle übrigen hervorgebracht werden.

> Apart from the known 54 chemical elements, there is only one agent in the physical world, and this is called energy; it can appear under the appropriate conditions as motion, chemical affinity, cohesion, electricity, light, heat, and magnetism, and from any one of these forms it can be transformed into any of the others.

Ludwig Mond (German, 1839–1909) developed and improved electrochemical methods for extracting and depositing nickel and other metals. Mond also founded the field of organometallic chemistry (p. 497).

Adolph Müller (German, 1852–1928) was responsible for first producing lead-acid storage batteries on an industrial scale in Germany in 1886. His battery company became known as Accumulatoren Fabrik Aktiengesellschaft Berlin-Hagen (AFA) until 1945, and as VARTA (Vertrieb, Aufladung, Reparatur transportabler Akkumulatoren) after 1945.

Walther Nernst (German, 1864–1941) was one of the founders of the field of physical chemistry. He made important discoveries regarding the statistical physics underlying thermodynamics, chemical reactions, electrochemistry, and the physics of solids. He derived the Nernst equation relating voltages and ion concentrations in electrochemistry. In 1905, he discovered the third law of thermodynamics (as a system approaches absolute zero temperature, its entropy approaches a constant value), for which he won the Nobel Prize in Chemistry in 1920 (p. 913).

Wilhelm Ostwald (German, 1853–1932) was another founder of the field of physical chemistry. He developed statistical methods that were applicable to thermodynamic processes in both chemistry and physics. He also made key discoveries regarding the dissociation constants of electrolytes (Ostwald's dilution law) and polymorphism in solid materials (Ostwald's rule). Ostwald's work earned him the Nobel Prize in Chemistry in 1909 (p. 913).

In 1842, Johann Christian Poggendorff (German, 1796–1877) invented an improved battery, now called the Poggendorff cell, that used chromic acid as the electrolyte. Poggendorff also developed and used a number of sensitive instruments for measuring voltage, current, and other parameters in electrochemistry experiments.

John Polanyi (German/Hungarian, 1929–) is the son of Michael Polanyi. He won the Nobel Prize in Chemistry in 1986 for developing methods of using infrared chemiluminescence and other techniques to make high-speed measurements of chemical reactions as they occur. The Royal Swedish Academy of Sciences explained his work [https://www.nobelprize.org/prizes/chemistry/1986/ceremony-speech/]:

> Chemical reactions in which molecules comprised of atoms collide and form new compounds represent one of nature's fundamental processes. At the end of the 1950s John Polanyi began developing methods to carefully study the dynamics of chemical reactions. During chemical reactions, the newly formed molecules are sometimes infused with energy that then is emitted in the form of infrared light. By measuring this very weak radiation, the quantum mechanical energy state of the molecules can be determined and the reaction mapped.

Michael Polanyi (Hungarian, 1891–1976) made major discoveries in many areas of physical chemistry, including the kinetics of chemical reactions, X-ray diffraction, the adsorption of gases by solids, fiber diffraction analysis, and the theory of dislocations in materials under plastic deformation. He also made important contributions in a number of other fields, including medicine, economics, philosophy, and epistemology. He was the father of John Polanyi. The American Council of Learned Societies summarized his contributions to physical chemistry [ACLS 2000, p. 717]:

> Earned his Ph.D. from the University of Budapest in 1917 with a dissertation on the thermodynamics of gas adsorption. In 1920 he was hired by the Kaiser Wilhelm Institute for Fiber Chemistry in Berlin, where he did research on plant fibers, using X-ray diffraction. At the Kaiser Wilhelm Institute for Physical Chemistry, which he joined in 1923, he established his well-known dislocation theory. His work with Eugene Wigner concerned the uncertainty principle for angular momentum and the absolute rate of unimolecular dissociation. In 1933 he immigrated to England, where his main work was in reaction kinetics. At the University of Manchester, he helped develop the theory of bimolecular activation energy and the theory of absolute rates of reaction; he also did studies on ionic reactions in solution, on bond dissociation energies, and on the mechanism of polymerization.

Hans Preis (Swiss, 18??–19??) worked together with Emil Bauer to develop the first fuel cell with a solid electrolyte, in this case one made of paste and metal oxides.

Johann Ritter (Prussian/Bavarian, 1776–1810) built the first or one of the first electrolysis cells around 1800 and studied the electrolysis of water. He also built and conducted experiments with very early batteries. In addition, Ritter discovered ultraviolet light in 1801 (p. 961).

Beginning in 1896, Paul Schmidt (German, 1868–1948, not to be confused with the later designer of the V-1 cruise missile's pulsejet engine) mass-produced zinc-carbon dry batteries and founded the Daimon electronics company.

Christian Schönbein (German states, 1799–1868) invented and demonstrated the first fuel cells (using hydrogen and oxygen) no later than 1838, as shown in Fig. 3.124. He also discovered ozone and did groundbreaking work in explosives (p. 528) and chromatography (p. 711).

Wilhelm Sinsteden (German, 1803–1891) invented and demonstrated lead-acid rechargeable batteries during the period 1850–1854, published his results in 1854 (Fig. 3.125), and studied many other areas of electricity and electrical components.

While Otto Stern (German, 1888–1969) is more famous for his physics experiments (p. 897), he made several important contributions to physical chemistry. He discovered what is now known as the Stern electrochemical double layer, developed the Stern-Volmer equation for photochemical reaction kinetics with Max Volmer, and studied entropy and statistical effects in chemical systems.

Ignatz Stroof (German, 1838–1920) developed industrial-scale electrolysis systems for producing chemical elements of high purity.

Julius Tafel (Swiss, 1862–1918) made several discoveries in electrochemistry that are now named after him, such as the Tafel equation relating voltage and the electrochemical reaction rate, the Tafel mechanism for catalytic hydrogen production, and the Tafel rearrangement for electrochemical hydrocarbon synthesis.

Jacobus van 't Hoff (Dutch, 1852–1911) was another founder of the field of physical chemistry, making vital discoveries regarding chemical affinity, chemical equilibrium, chemical kinetics, chemical thermodynamics, osmotic pressure in solutions, and stereochemistry. In 1901, he became the first winner of the Nobel Prize in Chemistry (p. 475).

Max Volmer (German, 1885–1965) made several contributions to physical chemistry. One was discovering what is now known as Volmer diffusion of adsorbed molecules. Working with Tibor Erdey-Grúz, he also developed an equation describing the relation between voltage and current in electrolytic solutions. With Otto Stern, he developed the Stern-Volmer equation describing the kinetics of photochemical reactions. Moreover, Volmer played an important role in the wartime German nuclear program (Section 8.8) and the postwar Soviet nuclear program (Section 8.9).

In 1874, Emil Wohlwill (German, 1835–1912) invented what is now known as the Wohlwill process, an electrochemical process for refining gold or silver to very high purity, which is still used today. He was the father of Heinrich Wohlwill.

Heinrich Wohlwill (German, 1874–1943) was the son of Emil Wohlwill. He invented an electrolytic process for purifying and recycling copper, and became the technical director of Norddeutsche Affinerie to apply that process on an industrial scale. Unfortunately he was taken to the Theresienstadt concentration camp in 1942 and died there in 1943.

Kurt Wüthrich (Swiss, 1938–) developed methods to use nuclear magnetic resonance (NMR) to study large molecules. For that work, he won the Nobel Prize in Chemistry in 2002. Professor Astrid Gräslund of the Royal Swedish Academy of Sciences emphasized the importance of his innovations [https://www.nobelprize.org/prizes/chemistry/2002/ceremony-speech/]:

> Using nuclear magnetic resonance, or NMR, a method that Kurt Wüthrich has further refined, it is now possible to determine the three-dimensional structure of protein molecules in a water solution. NMR is one of the chemist's best methods for examining molecules, and it has been used extensively for small molecules since the mid-20th century. But large molecules like proteins involve special problems. One of the fine points of NMR is that it enables us to see individual signals, for example, from each hydrogen nucleus in a molecule. But because a protein can contain thousands of hydrogen nuclei, how do you know which signal belongs to which nucleus?
>
> Wüthrich devised a way of systematically determining how each signal fits together with its special hydrogen nucleus. In the bargain, he was also able to determine a large number of pairwise distances between hydrogen nuclei. This enabled him to calculate a three-dimensional structure for the protein molecule. It is something like drawing a picture of a house if you know a large number of distances in the house. So thanks to Wüthrich's discovery, we can now use NMR to examine and depict proteins in their natural environment, surrounded by water like in a cell.

3.6.2 Batteries and Fuel Cells

Most modern battery and fuel cell technologies were invented and developed in the German-speaking world, as discussed above for individual creators and as shown in Figs. 3.124–3.130. Advanced German battery technologies were used for everything from the world's first hybrid electric automobiles in 1900 (p. 1353) to electric submarines in World Wars I and II (p. 1458).

Many of those battery technologies were transferred out of the German-speaking world before 1945 in the form of patents, commercial transactions, and immigrant scientists. However, there were a number of additional, advanced battery and fuel cell technologies that were transferred out of the German-speaking world in the immediate aftermath of World War II (Fig. 3.128), as shown by numerous reports such as:

> BIOS 307. *German Secondary Batteries (with Special Reference to Those Used by Army Signals).*

NavTecMisEu 310-45. *German Submarine Battery Installation and Battery Ventilation.*

Karl Kordesch and many other German-speaking experts on advanced battery and fuel cell technologies were also transferred along with all of that information.

In addition to battery and fuel cell technologies, many other physical-chemistry-based technologies were transferred too, such as physical methods of making chemical measurements. See for example:

Christian Schönbein (1799--1868) invented the first fuel cells (1838 or earlier)

X. *On the Voltaic Polarization of certain Solid and Fluid Substances. By Prof.* Schœnbein.

To the Editors of the Philosophical Magazine and Journal.

Gentlemen,

I READ a paper containing an account of the results of my researches on the voltaic polarization of solid and fluid bodies, before the scientific meetings which took place at Bâle and Fribourg, some months ago.

This memoir, I think, will soon be published in the *Biblioth. Univ.* and in Poggendorff's *Annalen*, and the scientific public thereby enabled to appreciate the facts related in it. The sort of investigations alluded to could not but lead me to make numerous experiments similar to those which were mentioned the other day in the French Academy, as performed by MM. Matteucci * and Peltier, of which I have however, up to this present moment, but a very imperfect knowledge. Having from want of time not yet been able to draw up a regular paper on the results of my most recent voltaic researches, and thinking them not quite void of scientific interest, I beg the favour of your giving in the forthcoming Number of your widely circulated Journal a place to the general statements, the tenor of which is as follows:

1. A platina wire polarized either in the positive or negative way loses its peculiar condition by being heated red-hot. (I call positively polarized a wire which has acted for some time the part of the negative electrode in water slightly acidulated by sulphuric acid; and I term negatively polarized a wire which has in the same liquid performed the function of the positive electrode.)

2. A platina wire positively polarized loses its peculiar condition by being plunged only for a single moment into an atmosphere of chlorine.

3. A platina wire positively polarized loses likewise its electromotive power by being placed in an atmosphere of oxygen; but in order to destroy entirely the polarity of the wire, it is necessary that it should remain for some seconds in the gas mentioned.

4. A platina wire negatively polarized loses its peculiar condition by being put into an atmosphere of hydrogen, but in order to obtain this effect, it is required that the wire in question should remain for some seconds in the gas.

5. A platina wire polarized either negatively or positively is not sensibly affected by being placed in an atmosphere of

carbonic acid or in one of any other gas which does not chemically act either upon hydrogen or oxygen.

6. A platina wire (in its natural state) assumes in every respect the condition and voltaic bearings of a positively polarized wire by being plunged only for a few seconds into an atmosphere of hydrogen.

7. Gold and silver are not sensibly affected under the same circumstances.

8. A platina wire does not acquire any degree of electromotive power by being put into oxygen gas: the metal remains in its natural state. Neither is any degree of such power acquired by gold or silver under the same circumstances.

9. Platina, gold, and silver, by being placed only for a few seconds in an atmosphere of chlorine, assume the voltaic state of a negatively polarized wire.

10. Water slightly acidulated with sulphuric acid and holding some hydrogen dissolved, bears to acidulated water containing no hydrogen the same voltaic relation that zinc does to copper; provided, however, both fluids be separated from each other by a membrane, and connected with the galvanometer by means of platina wires. If for the latter purpose (that is to say, for connecting the fluids with the galvanometer) gold or silver wires are made use of, the said fluids do not excite the least current.

11. Two fluids, one being acidulated water containing some oxygen dissolved, the other being likewise acidulated water containing no oxygen, appear to be in a voltaic point of view perfectly indifferent to each other, whether they are connected with the galvanometer by platina, silver, or gold wires.

12. Water slightly acidulated with sulphuric acid and holding some chlorine dissolved, bears to acidulated water not containing any chlorine the same voltaic relation that copper bears to zinc. In other terms, the former fluid acts under certain circumstances the electromotive part of the peroxides of silver, lead, &c.

13. The aqueous solution of hydrogen mentioned in § 10, loses its property to excite a current by being mixed with a certain quantity of an aqueous solution of chlorine; and, *vice versâ*, the latter fluid loses its electromotive power mentioned in the § 12 by being mixed with a sufficient quantity of hydrogen dissolved in water.

14. Muriatic acid positively polarized loses its peculiar voltaic condition by being mixed with some chlorine, and the same acid being negatively polarized loses its polarity by being treated with some hydrogen. From the facts stated, and

others which are mentioned in the memoir above alluded to, a great number of rather important inferences might be drawn; but having for the present no leisure time to do so, I am obliged to confine myself to stating those which follow:

a. The secondary currents produced both by polar wires, electrolytic fluids, and secondary piles, are due to chemical action, i. e. (in the cases mentioned) to the union of oxygen with hydrogen, or to that of chlorine with hydrogen; and not, as M. Peltier seems to think, to the mere act of the solution in water of the gases mentioned.

b. The chemical combination of oxygen and hydrogen in acidulated (or common) water is brought about by the presence of platina in the same manner as that metal determines the chemical union of gaseous oxygen and hydrogen.

c. The current produced by a platina wire being surrounded by a film of chlorine, or by water holding chlorine in solution, is not dependent on the action of the latter body upon platina, but on the action of chlorine upon the hydrogen of water.

d. Electrolytic bodies do not suffer even the weakest current to pass through them without undergoing decomposition. (This inference is drawn from the fact ascertained by me some time ago, that platina wires acting as electrodes in muriatic acid are polarized by a current so weak as not to be able to electrolyze even iodide of potassium).

e. The most delicate test to ascertain that electrolyzation has taken place, is the polarized state of the electrodes.

I cannot close my letter, Gentlemen, without taking the liberty to point out to you the beautiful, and, as it seems to me, most conclusive evidence in favour of the correctness of the chemical theory of galvanism, now so much contested, which is afforded by the fact stated in § 10. If the mere contact of the two different fluids mentioned there were the real cause of the current obtained, it is obvious that the same current ought to be produced whether the fluid be connected with the galvanometer by means of gold, or if they be connected with the instrument by that of platina wires; but the result being determined by the nature of the connecting wires, and platina being known to favour the union of hydrogen and oxygen, whilst gold and silver do not possess in any sensible degree that property, we are entitled to assert that the current in question is caused by the combination of hydrogen with (the) oxygen (contained dissolved in water) and not by contact.

I am, Gentlemen, yours, &c.

Bâle, Dec. 1838. C. F. Schœnbein.

1854. ANNALEN No. 1.

DER PHYSIK UND CHEMIE.

BAND XCII.

I. *Versuche über den Grad der Continuität und die Stärke des Stroms eines gröſsern magneto-elektrischen Rotations-Apparats und über die eigenthümliche Wirkung der Eisendrahtbündel in den Inductionsrollen dieser Apparate;*

von Dr. Sinsteden.

1.

Der Strom der Saxton'schen Maschine wird gemeinhin als ein discontinuirlicher und in jedem Zeitmoment sich selbst *nicht* gleichbleibender Strom bezeichnet, und in dieser Hinsicht dem continuirlichen und in sich homogenen Strome der hydroelektrischen Batterie entgegengestellt. In welchem Grade aber der Strom der Saxton'schen Maschine discontinuirlich und ungleichmäſsig sey, hat man bisher durch Versuche noch nicht festgestellt; noch weniger ist man viel bemüht gewesen, ihn möglichst continuirlich und homogen zu machen. Man hat sich vielmehr auf entgegengesetztem Wege zu helfen gesucht, wenn es darauf ankam, der Discontinuität des Stroms und dem dadurch, z. B. bei Versuchen mit dem Multiplicator, verursachten Schwanken der Nadel zu begegnen, indem man nämlich die Nadel durch in Oel tauchende Platinflügel schwerbeweglich machte, wodurch sie zum festeren Einstehen gebracht wurde. Daſs die *besondere* Einrichtung des Saxton'schen Apparats auf den Grad der Stromcontinuität den gröſsten Einfluſs hat, habe ich schon früher in diesen Annalen Bd. 76, S. 527 gezeigt.

Der Strom des ebendaselbst Bd. 84, S. 181 beschriebe-

UNITED STATES PATENT OFFICE.

CARL GASSNER, JR., OF MENTZ, GERMANY.

GALVANIC BATTERY.

SPECIFICATION forming part of Letters Patent No. 373,064, dated November 15, 1887.

Application filed May 20, 1887. Serial No. 238,909. (No specimens.) Patented in Germany April 8, 1886, No. 37,758; in Austria-Hungary May 21, 1886, No. 35,974 and No. 64,357; in Belgium July 16, 1886, No. 73,872; in France July 17, 1886, No. 177,465, and in England December 22, 1886, No. 16,810.

To all whom it may concern:

Be it known that I, CARL GASSNER, Jr., of the city of Mentz and Empire of Germany, have made a certain new and useful Improvement in Galvanic Elements, of which the following is a specification.

My invention relates to galvanic elements; and it consists in the intermixture and employment of oxide of zinc as an addition to the exciting agent for galvanic elements, substantially as hereinafter described and claimed.

The oxide of zinc may be employed with great advantage as a constituent of any well-known exciting agent for the elements, with which it can be mechanically mixed and introduced into the galvanic cell and act therein, as hereinafter set forth. I do not, however, claim its employment when mixed with an exciting-fluid for the electrodes and applied thereto before being introduced into the cell, so as by chemical action to transform the zinc oxide at once into a chemically-different salt—as, for instance, dilute sulphuric acid—which transforms it into zinc sulphate.

I have found that the method of mixing and employing the zinc oxide set forth in the following description gives good results; but I do not confine my invention to the precise ingredients or proportions of the other constituents thereof named, as it is evident that well-known equivalents may be employed, and that the proportions of the other ingredients and of the zinc oxide may be advantageously varied, according to the different galvanic action required, whether constant or intermittent, even or varying. The essential requisite of securing the presence of the zinc oxide in the exciting agent while acting upon the electrodes must, however, be preserved.

The form of element I prefer to employ is composed of a zinc cylinder containing an isolated cylinder of carbon manganese, between which two cylinders exists a space which is filled up with the exciting agent, in liquid or semi-liquid form, which after awhile becomes comparatively hard and solid. This agent is made up, according to my improvement, preferably of the following ingredients, in the proportions stated, namely: oxide of zinc, one (1) part, by weight; sal-ammoniac, one (1) part, by weight; plaster, three (3) parts, by weight; chloride of zinc, one (1) part, by weight; water, two (2) parts, by weight. The oxide of zinc in this composition has this effect, after it is introduced into the cell—viz., that it loosens and makes it porous, and the greater porosity thus obtained facilitates essentially the interchange of the gases and diminishes the tendency to the polarization of the electrodes.

The inner resistance of the elements will not be raised by the addition of the oxide of zinc, as the latter is a better conductor of electricity than plaster and other similar bodies, which produce only a partial and varying porosity.

Elements combined with oxide of zinc in the galvanic cell, substantially as hereinbefore described, are of a much superior constancy.

What I claim as new and of my invention is—

In a galvanic battery, the combination of zinc oxide with the exciting agent, the oxide being in a state of mechanical mixture or distribution throughout the mass of said exciting agent, substantially as described.

ERNST WALDEMAR JUNGNER in STOCKHOLM.

Verfahren zur Herstellung negativer Elektroden für Accumulatoren mit unveränderlichem Elektrolyten.

Angemeldet am 16. März 1900.
Beginn der Patentdauer 15. Juni 1901.

Die vorliegende Erfindung bezweckt die Herstellung einer negativen Elektrode, die mit besonderem Vortheil bei dem in dem österreichischen Patente Nr. 3853 gekennzeichneten Accumulator angewendet werden kann.

Es ist bekannt, dass die Chloride von Zink und Magnesium sich mit den Oxyden derselben Metalle zu basischen, unlöslichen Chloriden (Oxychloriden) vereinigen.

Dies ist auch der Fall mit dem Chloride des, den genannten Metallen verwandten, Metalles Cadmium. Wird Cadmiumoxyd mit einer Lösung von Cadmiumchlorid zu einem dicken Brei angerührt, so erstarrt diese Mischung zu einer harten kittartigen Masse, welche aus Oxychloriden von verschiedenartiger Zusammensetzung (z. B. $Cd_4O_3Cl_2$) besteht. Auch andere Cadmiumsalze z. B. Cadmiumsulfat haben in dieser Beziehung dieselbe Eigenschaft wie Cadmiumchlorid.

Für denselben Zweck können auch Salze anderer Metalle Verwendung finden, sofern diese nur mit Cadmiumoxyd basische Verbindungen bilden und sich mit diesem Körper in der Weise umsetzen, dass das Säureradical des Salzes sich mit dem Cadmium vereinigt, während dessen Metallradical sich mit dem Sauerstoffe des Cadmiumoxydes bindet.

Wird z. B. Kupferchlorid verwendet, so erfolgt folgende Reaction:

$$CuCl_2 + CdO = CuO + CdCl_2.$$

Ist dabei das Cadmiumoxyd in Ueberschuss vorhanden, so vereinigt sich dasselbe mit dem gebildeten Cadmiumchlorid zu einem festen Kitt.

Wie bekannt, ist die Festigkeit einer derartigen kittartigen Masse umso größer, je langsamer die chemischen Reactionen zur Zusammenbindung derselben vor sich gehen. Es ist daher im vorliegenden Falle vortheilhaft ein solches Salz zu verwenden, welches nur sehr langsam mit dem Cadmiumoxyd eine chemische Verbindung eingeht. Ein solches Salz ist z. B. Chlorammonium. Bei Verwendung dieses Salzes treten die folgenden Reactionen ein:

$$2NH_4Cl + CdO = 2NH_3 + H_2O + CdCl_2 \text{ und}$$
$$CdCl_2 + 3CdO = Cd_4O_3Cl_2.$$

Die Herstellungsweise der in Frage stehenden Elektroden ist folgende:

Auf einem Netz oder einem perforierten Bleche aus einem Metalle, welches sich zu dem verwendeten Elektrolyten chemisch indifferent verhält (z. B. Kupfer) wird das Cadmiumoxyd, welches mit Wasser, unter Zusetzung einer kleinen Menge von Chlorammonium zu einem Brei angerührt worden ist in einer Schichte aufgetragen. Sobald die Masse trocken ist, wird das Netz oder das Blech während eines Zeitraumes von 2—50 Stunden in eine Lösung von Chlorammonium eingetaucht, wobei das Cadmiumoxyd nach der beschriebenen Reaction in einen festen Kitt umgewandelt wird.

Klasse 21 b. Ausgegeben am 10. August 1905.

Österreichische

PATENTSCHRIFT Nr. 20869.

ERNST WALDEMAR JUNGNER in NORRKÖPING (SCHWEDEN).

Verfahren, um Eisen, Nickel und Kobalt als Masseträger für Sammlerelektroden geeignet zu machen.

Angemeldet am 20. September 1901. — Beginn der Patentdauer: 1. März 1905.

Vorliegende Erfindung betrifft ein Verfahren, um Eisen, Nickel und Kobalt, deren sämtliche Oxyde bekanntlich nur wenig oder gar nicht leitend und in Ätzalkalien völlig unlöslich sind, durch Vergrößerung ihrer Oberfläche als Masseträger für Elektroden in alkalischen Sammlern, für welche sie bisher keine Verwendung finden konnten, aber ausschließlich nur verwendbar sind, geeignet zu machen, und zwar auf elektrolytischem Wege, da eine nur mechanische Aufrauhung hiefür sich nicht als ausreichend erwiesen hat, indem es bei diesen Metallen im besonderen darauf ankommt, daß möglichst alle Teile der wirksamen Masse in unmittelbarer Berührung mit dem Masseträger stehen.

Dieser Zweck kann gemäß der vorliegenden Erfindung des weiteren aber nur dadurch erreicht werden, daß man auf diese Metalle als Anoden einen besonderen alkalischen Elektrolyten einwirken läßt, nämlich einen solchen, der neben dem Ätzalkali noch ein Salz enthält, dessen Säureradikal mit diesen Metallen lösliche Salze bildet. Es könnte der beabsichtigte Zweck nicht erreicht werden, wenn man diese Metalle als Anoden nur in die Lösung eines Ätzalkalis bringen würde. Hiebei können sich diese Metalle mit einer nur dünnen Oxydschicht überziehen, welche sie vor dem weiteren Angriff des Elektrolyten schützt, da die gebildete Oxydschicht eben in Alkali unlöslich und nicht leitend ist. Würde man dagegen einen die Anode bezw. das gebildete Oxyd lösenden Elektrolyten zur Anwendung bringen, so würde die Oberfläche dieser Metalle von dem Elektrolyten an jedem Punkt angegriffen werden, wobei höchstens nur eine oberflächliche, aber keine tiefer gehende Aufrauhung bezw. Vergrößerung der Oberfläche stattfindet, welche nur einer mechanischen Aufrauhung gleichkäme. Zur Herstellung von Bleisammlerelektroden aus bekannten Bleiplatten hat man zwar schon einen salzhaltigen, schwach alkalischen, sauren oder neutralen Elektrolyten vorgeschlagen, allein hiebei wird ein anderer Zweck beabsichtigt und werden andere Wirkungen erzeugt, da das gebildete Bleioxyd in Ätzalkalien löslich und ein relativ guter Leiter ist, so daß bei solchen Bleielektroden die Vergrößerung der Oberfläche nicht die wesentliche Bedingung ist. Eine solche wird auch, wie experimentell festzustellen ist, nicht erreicht. Das vorliegende Verfahren beruht somit auf einer neuen Erkenntnis. Die besondere Wirkung des Verfahrens besteht darin, daß auf dem Träger aus Eisen, Nickel oder Kobalt eine schwamm- oder moosartige metallische Oberfläche gebildet wird, die man sich derart entstanden denken kann, daß in den Wandungen der zuerst erzeugten Vertiefungen neue Vertiefungen gebildet werden, deren Wandungen wiederum vertieft werden und sofort, indem die Bildung der Metallverbindung in den Elektrolyten der vorliegenden Art schneller vor sich geht, als deren Auflösung. Um dieses auch tatsächlich zu erreichen, muß der Elektrolyt derart zusammengesetzt sein, daß einerseits die gebildete Metallverbindung im Elektrolyt nicht so schwer löslich ist, daß sie an der Oberfläche der Elektrode eine zusammenhängende, dichte Schichte bildet, welche die weitere Einwirkung des Elektrolytes verhindert und daß anderseits die gebildete Metallverbindung nicht in solchem Grade löslich ist, daß jedes Molekül im Augenblick seiner Bildung sofort aufgelöst wird. Ferner hängt die mehr oder minder gute Beschaffenheit der erzeugten Oberflächenvergrößerung von der Stromdichte, Temperatur des Elektrolyten, der Entfernung der

Ernst Waldemar JUNGNER, in Stockholm (Schweden).

Primär wie sekundär benutzbares galvanisches Element.

Viele Mängel der bisherigen primären wie sekundären galvanischen Elemente lassen sich im allgemeinen darauf zurückführen, daß der Elektrolyt beim Durchgange des Stromes in Bezug auf chemische Zusammensetzung oder Koncentration Veränderungen erleidet.

Hieraus folgt auch, dass die Bestandteile des Elektrolyten wie die der wirksamen Masse der Elektroden in ihrem Aggregatzustande verändert werden. Der Bleiakkumulator, sowie auch das Lalandsche sekundäre Element bilden in dieser Beziehung eine Ausnahme nur insofern, als der Elektrolyt allerdings der chemischen Beschaffenheit nach nicht geändert wird, wohl aber in Bezug auf Konzentration und Volumen. Das in dem ersteren Falle in dem Bleisulfat befindliche Radikal (SO_4) wie das eine im letzteren Falle im Eisenoxydhydrat ($Fe[OH]_3$) befindliche Hydroxydradikal (OH) bilden beim Durchgang des Stromes den Bestandteil bald eines flüssigen, bald eines festen Stoffes. Eine Änderung des Elektrolyten ist auch bei Cailletets und Collardeaus Gaskompressionselementen mit Platinelektroden vorhanden.

Die vorliegende Erfindung betrifft dem gegenüber ein primär wie sekundär benutzbares galvanisches Element, in welchem der Elektrolyt sich weder in seiner Zusammensetzung, noch in seiner Koncentration ändert. Es spielt hiernach der Elektrolyt nur die Rolle eines Leiters zwischen den Elektroden, und es braucht, da er ja nicht zersetzt wird, nur eine verhältnismäßig geringe Menge desselben in das Element gefüllt zu werden.

Zu diesem Zweck besteht der Elektrolyt aus einem in Wasser löslichen Hydrat irgend eines Metalles, dessen Metallradikal Wasser zerlegt; also z. B. aus einem Alkalihydrat.

Bei der Elektrolyse einer Lösung von Kalihydrat finden bekanntlich folgende Reaktionen statt:

$$\begin{array}{l} \begin{matrix}KOH\\KOH\end{matrix} = \left\{\begin{matrix}K\\K\end{matrix}\right. + \left\{\begin{matrix}OH\\OH\end{matrix}\right. \\ \hline \left\{\begin{matrix}K\\K\end{matrix}\right. + \left\{\begin{matrix}HOH\\HOH\end{matrix}\right. = 2KOH + H_2 \\ \left\{\begin{matrix}OH\\OH\end{matrix}\right. = H_2O + O. \end{array}$$

Man ersieht hieraus, daß die chemische Zusammensetzung des Elektrolyten unverändert bleibt und daß das Ergebnis eine einfache Zersetzung und Wiederbildung von Wasser ist.

Die wirksamen Massen bestehen im wesentlichen aus einem im Elektrolyten unlöslichen, nicht Wasserstoff freimachenden, fein zerteilten

NICKEL CADMIUM STORAGE BATTERIES
IN GERMANY

OFFICE OF MILITARY GOVERNMENT
FOR GERMANY (US)

FIELD INFORMATION AGENCY TECHNICAL

INTRODUCTION

Objective:

Nickel cadmium storage batteries were not manufactured in the United States nor were they commercially available until early in 1946. A study was made of the developments and methods in Germany where "AFA" (Accumulatorenfabrik, A. G. Hagen and Hannover) the foremost producer, has been making them for many years.

Evaluation:

Nickel cadmium storage batteries are batteries of the alkaline type and have electrical characteristics suiting them to all purposes where the use of a storage battery is indicated. The alkaline storage battery industry in Europe is familiar with the production methods given here, but many of these are new to the United States. Of particular interest are the methods for producing the nickel and cadmium active materials, and the new DURAC cells with porous, sintered plates. The following is the approximate sales volume of nickel cadmium storage batteries by "AFA":

1935	5 million Ampere-hours	1940	22 million Ampere-hours
1936	7 million "	1941	29 million "
1937	10 million "	1942	25 million "
1938	14 million "	1943	23 million "
1939	17 million "	1944	26 million "

Various Types of Cells Manufactured:

Cells with tubular pocket positive and flat pocket negative plates. Cells having the nickel positive active materials in tubular pockets attain the longest life of all nickel cadmium batteries. They have the advantage of maximum capacity in relation to size and weight. Their capacity increases about 10% over the initial 30-40 discharges. On the other hand, tubular plates have a higher internal resistance than flat pocket plates and, consequently, a larger voltage drop at high rates of discharge. They are, therefore, recommended for applications where the current required does not greatly exceed the five-hour rate of discharge. The initial cost of a tubular pocket battery is higher than that of a flat pocket one.

Cells with flat pockets only. These weigh more and take up more space than cells with tubular pocket plates, the amount depending

AIR-DEPOLARIZED CELL
Karl Kordesch, Lakewood, Ohio, assignor to Union Carbide Corporation, a corporation of New York
Filed Mar. 12, 1958, Ser. No. 721,030
9 Claims. (Cl. 136—86)

This invention relates to an air-depolarized cell employing an alkaline electrolyte in conjunction with a gelled anode.

The main object of this invention is to provide an air-depolarized cell operable at good currents, and satisfactory voltages, at temperatures as low as —20° C.

Another object of the invention is to provide a novel anode collector.

In the drawings:

Fig. 1 is a vertical section of a cell in accord with the invention; and

Fig. 2 contains a series of curves showing the performance of such a cell.

The cell of the invention comprises a centrally apertured container, an anode gel mixed with electrolyte, and a separator-lined cathode protruding above the container. This cathode is treated, prior to cell assembly, by one of the processes disclosed in U.S. Patents 2,615,932 and 2,669,598 issued to A. Marko and K. Kordesch.

The processes claimed in the mentioned patents involve impregnating porous carbon with a solution containing at least one heat decomposable salt of a heavy metal such as iron, cobalt, nickel, manganese, chromium, copper, silver, gold, platinum, vanadium, titanium, uranium, thorium and the rare earths, and at least one heat decomposable salt of aluminum, the enumerated salts acting as oxidizing agents for carbon. Following impregnation with above-described solution, the treated carbons are heated to decompose the salts, thereby activating and catalyzing them. Following this treatment, the carbon contains within its pores and at the surface thereof a spinel type catalyst consisting of an oxide of the heavy metal and of aluminum oxide ($RO \cdot Al_2O_3$). This treatment will be more fully described hereinafter.

Cathode fabrication

The cathodes used in the cells of the invention may be prepared from a mixture consisting of about 60 percent by weight of projector type carbon, about 40 percent by weight of soft pitch and about 1½ percent by weight of fuel oil. Tubes having the desired dimensions are extruded from such a mix and baked at 1000° C. for about 6 hours. After this baking the tubes have a porosity of between 20 and 33 percent, using water saturation method measurements. The tubes are next heated in a CO_2 atmosphere between 850° C. and 950° C. for two hours to convert their hard and shiny skin to a surface having a dark black appearance. In this condition the carbon tubes are better able to absorb the catalyzing solution in which they will be immersed. Such a solution may consist of an 0.1 molar solution of aluminum nitrate and cobalt nitrate containing 75 g. $Al(NO_3)_3 \cdot 9H_2O$ and 29 g. $Co(NO_3)_2 \cdot 6H_2O$ per liter. Generally one carbon cathode requires about 3 ml. of solution. Best results have been obtained by placing the carbon dioxide-treated carbon tubes, once cooled, in a container which is then evacuated. After obtaining a vacuum of about 20 millimeters of mercury, the catalyzing solution is allowed to enter the container, and to soak the electrodes. Upon restoring the air pressure, the solution is pressed into the pores of the tubes. The tubes are then dried at 100° C. for two hours, and heated again to 850° C. for two hours in carbon dioxide to decompose the metal nitrates to oxides. After this treatment a spinel of the formula $CoO \cdot Al_2O_3$ is formed from the catalyst mixture. The deposit is observable on the surface of the carbon tubes as a blue deposit. After cooling the carbon tubes in a carbon dioxide atmosphere, the vacuum operation and heating cycles are repeated to increase the activity of the carbon surface. A third cycle of treatment is not necessary, except for high current electrodes of a capacity of 100 milliamperes per centimeter squared, or more.

2

For best results the carbon electrode tubes should be wet-proofed. This can be achieved by immersing the tubes in a 1.5 percent paraffin petroleum ether solution for about five minutes. Following this the electrodes are air dried by passing air through their center. Wet-proofing affects the polarization of the electrode, but too much wet-proofing is detrimental to electrode life since it permits accumulation of hydrogen peroxide which accelerates carbon oxidation, and in some cases destroys the wet-proofing agent (for example, paraffin can be oxidized to fatty acids by nascent oxygen in the presence of heavy metal catalysts). As an additional wet-proofing, a mixture of equal parts of nitro-benzene and kerosene is applied to the inside of the tubular carbon electrode. The very dense inner surface of the electrode does not take up an appreciable amount in a short time. However, the vapors of the compounds mentioned travel to the active outer surface, and are adsorbed there to give the desired degree of repellency.

Other wet-proofing agents can be used in addition to paraffin and petroleum ether. Thus chloronaphthalene and dibenzylether may be used.

Anode construction

To achieve the highest possible capacity in a given volume, a powder zinc anode is used. Thirty percent of the zinc particles in this powder should be between 20 and 30 mesh (Tyler) in size; 30 percent between 60 and 100 mesh; another 30 percent should be between 100 and 200 mesh, and the rest is through 200 mesh. This powder is first coated with sodium carboxymethyl cellulose in such a way that a zinc powder carboxymethyl cellulose-water gel is formed. The gel is pressed into thin rods, dried and crushed to a particle size of 12 to 20 mesh. This material is coarse enough to allow the electrolyte to penetrate between the particles. During activation with electrolyte, the carboxymethyl cellulose coating swells, and forms a homogeneous gel anode.

The zinc powder should be amalgamated with from 2 to 4 percent of mercury. Amalgamation is best carried out in a 5 percent ammonia solution by adding the necessary amount of mercury to zinc powder. Vigorous stirring facilitates fast and uniform amalgamation. Amalgamated zinc powder is then washed once or twice with water, and dried in a vacuum at a moderate temperature (40 to 50° C.).

Electrolyte

Potassium hydroxide is the preferred electrolyte for the cells of the invention, especially in respect to low temperature service. Nine normal potassium hydroxide solution was found superior to six normal solution for such application.

Separator

Suitable separator materials include copolymers of vinyl chloride and acrilonitrile, parchment paper, caus-

ELECTROLYTES FOR RECHARGEABLE DRY CELL
Karl Kordesch, Lakewood, Ohio, assignor to Union Carbide Corporation, a corporation of New York
No Drawing. Filed June 17, 1958, Ser. No. 742,489
6 Claims. (Cl. 136—155)

This invention relates to electrolytes for use in conjunction with rechargeable dry cells of the alkaline type.

In my co-pending application entitled "Rechargeable Dry Cell," Serial No. 689,083, filed October 9, 1957, there is described a rechargeable dry cell comprising an hermetically sealed metallic container serving as the positive terminal thereof, a tubular cathode consisting of carbon and manganese dioxide particles fitting in the container, finely divided zinc particles mixed with alkaline electrolyte separated therefrom by means of a fibrous separator and contact means reaching the zinc particles. This cell is protected against accumulation of gas on overcharge by the recombination reaction occurring between the zinc particles and the oxygen formed during overcharging. This protection is effective only in those cells having a sufficiently large anode surface available for the oxygen to react with the zinc.

Similarly when a discharged cell of the type above outlined and having an amalgamated zinc anode is recharged, the pure zinc being redeposited at the anode should be spontaneously amalgamated. In those instances where this reaction does not occur, the pure zinc and the amalgamated zinc will form local galvanic cells yielding from 20 to 40 millivolts with consequent resulting corrosion and gassing of hydrogen. Some producers of rechargeable alkaline dry cells solve this problem by omitting the amalgamation of the zinc. This practice considerably reduces the shelf life of charged cells.

The main object of the present invention then is to provide means for preventing the development of excessive gas pressure on overcharging of rechargeable alkaline dry cells, which means will also facilitate the rapid amalgamation of redeposited zinc.

This object is attained in the practice of the invention by adding to an alkaline electrolyte consisting of a hydroxide of an alkali metal elemental iodine or an iodine-containing material. Typical electrolytes included within the scope of the invention are potassium hydroxide and sodium hydroxide. Suitable iodine-containing compounds are iodine, zinc iodide, sodium iodide and potassium iodide. These are used in an amount ranging from 5 percent to their saturation point in the given electrolyte.

Overcharge protection is obtained in accordance with the invention by the electrolytic production of iodine. The recombination reaction of iodine and zinc occurs more easily than that of oxygen and zinc, probably because of the formation of a metal-iodine-oxygen compound in the electrolyte which diffuses through the separator to the zinc anode where oxidation of zinc occurs.

Amalgamation can proceed by surface transport in mechanical contact or chemically by diffusion of Hg ions present in the electrolyte. Their presence is easily obtained in acidic electrolytes either by a simple dissolving of a small quantity of mercury from the amalgamated zinc upon contact with the electrolyte or by the direct addition of a salt of mercury to the electrolyte. These techniques will not work when an alkaline electrolyte is employed, since the Hg^{++} ion concentration in caustic solution is too small. Mercuric oxide precipitates out of KOH when a salt of mercury is dissolved therein. However, the $(HgI_4)^{--}$ complex is stable in caustic solution (e.g., in Nessler's reagent, which consists of KI and $HgCl_2$

2

in a KOH solution) and is quite suitable for amalgamating zinc in the $MnO_2/KOH/Zn$ cell.

K_2HgI_4 may be produced by adding KI to $HgCl_2$ until HgI_2 precipitates. The HgI_2 is then separated by filtration and dissolved completely in KI solution to form K_2HgI_4 which is compatible with KOH. An alternate method of obtaining the iodine complex in KOH involves the simple addition of iodine, KI, or ZnI_2 which forms the complex ion upon contact with the amalgamated zinc surface.

In the practice of this invention, it was demonstrated that amalgamated zinc in contact with an unamalgamated zinc sheet did not gas in KOH electrolyte when the $(HgI_4)^{--}$ ion was present. The voltage difference dropped within 5 seconds from 20 to 40 mv. to 5 mv. or less.

Experimentation also demonstrated the effectiveness of the iodide compound in preventing oxygen accumulation and resultant sealing failure of the cells. On charge, the KI in KOH was decomposed at about 1.7 volts (vs. zinc) and iodine was formed at the positive (MnO_2) electrode. The voltage did not rise above 1.75 volts.

To demonstrate the success of the invention, a total of 18 cells containing 12 N KOH electrolyte saturated with ZnI_2 was tested for one month. Half of these cells were assembled with a semi-permeable separator between layers of fibrous separators. These cells did not develop excessive gas pressure, and exhibited superior performance, namely 0.1 volt higher output than the other cells containing the fibrous separators only. Iodide decomposition apparently prevented the voltage from rising above 1.80 volts on overcharge.

In contrast, similar cells made with semi-permeable membrane separators show approximately 50 percent sealing failures on overcharge.

No detrimental effect of the iodide addition in respect to capacity or shelf behavior has been observed. As is the case with all cells utilizing chemical recombination reactions, the overcharge current must not exceed the equivalent of the transportation rate. It is still possible to explode a cell by accumulation of gas if the charge current is in excess of the diffusion speed of iodine through the separator to the zinc anode. However, iodine diffusion was found to be fairly rapid so that a normal charging rate of approximately 200 to 300 ma. is permissible (500 ma. seems to be the limit for a D-size cell).

The concentration of the iodide material does not appear to be critical except that sufficient iodide should be present to allow for some adsorption of iodide at the cathode. After the initial saturation of the cathode occurs, the excess iodine migrates to the zinc anode and recombines with the zinc. Thus, the minimum amount of iodide necessary is rather difficult to determine since it depends upon the porosity of the MnO_2 cathode. KI, ZnI_2 or I_2, all of which are quite soluble in concentrated KOH, may be added to the solution. Any of the compounds are suitable, although it appears simpler to employ ZnI_2. The KOH electrolyte is normally saturated with ZnO (zinc ions constitute an additional precaution against H_2 evolution on overcharging); therefore, the use of ZnI_2 is similar amounts avoids the necessity of adding both ZnO and KI or I_2.

What is claimed is:

1. In a rechargeable dry cell employing as an electrolyte an aqueous solution of a hydroxide of an alkali metal in conjunction with a cathode having manganese dioxide and an anode consisting of zinc, the improvement consisting in adding to said electrolyte an iodine-containing compound, said compound being present in the range of from 5 percent of said electrolyte to its saturation point in said electrolyte, said compound tend-

3,042,732
ANODES FOR ALKALINE CELLS
Karl Kordesch, Lakewood, Ohio, assignor to Union Carbide Corporation, a corporation of New York
Filed Oct. 14, 1959, Ser. No. 846,420
10 Claims. (Cl. 136—30)

This invention relates to alkaline primary and secondary cells, and more particularly, to improved anodes for use therein.

Powdered zinc anodes are capable of high discharge currents with alkaline electrolytes. The shelf life is also good, and therefore, such anodes are excellent partners for heavy duty cathodes such as manganese dioxide, nickel oxide, mercuric oxide and silver oxide in alkaline cells. For clarity's sake, the following discussion will be limited to the alkaline-manganese dioxide-zinc systems, but it is to be understood that the principles taught are equally applicable to the other alkaline systems mentioned above.

Unfortunately, when a cell is discharged beyond the depolarizing capacity of the manganese dioxide while having some active zinc remaining, the cell will tend to gas as a result of a corrosion couple formed between the carbon cathode and the zinc. Cell closure failures often occur as a result of such gassing. Similar situations occur when cells having slightly different capacities are employed in a multi-cell battery. Polarity reversals or over discharging and gassing occur in cells which reach complete discharge before others.

To prevent the above from occurring, it is common practice in the alkaline-manganese dioxide cells which are presently being constructed, to have the service life of the cell limited by the anode. Due to this feature, cells which are completely discharged have no remaining metallic zinc to initiate gassing. Unfortunately, this protective feature creates additional difficulties when a rechargeable version of an alkaline-manganese dioxide-zinc cell is constructed. The gelled zinc anodes, which are commonly employed in such cells, accept recharge poorly, if at all, if the cell is discharged completely. This problem cannot be solved simply by the addition of extra zinc to the anode, since this in turn, will lead to gassing after the depolarizer has become exhausted. For these reasons, it has been necessary in the past to provide special equipment for arbitrary control and limitation of the discharge depth of rechargeable cells, such as automatic voltage or cycle-time cut-offs.

The principal object of the invention is to provide chemical means for the control of the discharge of primary and secondary alkaline-manganese dioxide-zinc cells thus eliminating the need for special equipment for the control of discharge depth.

A further object of the invention is to provide an improved matrix for the replating of zinc upon the recharging of discharged alkaline cells.

Broadly stated, the objects of the invention are accomplished by an improved anode composition which comprises, in addition to powdered metallic zinc, one or more of the following: lead oxide, copper oxide, metallic copper or metallic magnesium. The addition of any one of these materials to a zinc anode will prevent gassing and irreversible damage to both primary and rechargeable cells on deep discharge. In addition, these added

2

materials serve as an excellent matrix for the replating of zinc upon recharging of the cell.

The invention will be more readily understood by referring to the accompanying drawing wherein

FIG. 1 is a greatly enlarged cross-section of an anode embodying the principles of the invention, and

FIG. 2 is a greatly enlarged cross-section of another anode which embodies the principles of the invention.

More specifically, in the practice of the invention, lead oxide, copper oxide, metallic copper or metallic magnesium is intermixed with powdered metallic zinc to form an anode. While the use of any one of these materials in admixture with zinc results in an improved anode, there are slight differences in each and the improved anode which may be formed from a mixture of powdered zinc and each of the stated materials will be discussed separately.

When powdered zinc and lead oxide are mixed in an alkaline electrolyte, interaction occurs between the two and a portion of the zinc reduces the lead oxide to spongy lead and simultaneously forms zinc oxide which goes into solution as zincate. No gassing can occur on deep discharge in a cell containing an anode of this composition since the voltage difference between lead/lead oxide and partially discharged manganese dioxide diminishes to zero. If such a cell is accidentally reversed, lead oxides are formed. If this cell is connected in series with similar cells which are not reversed, a plateau in the reverse charging curve occurs in the reversed cells prior to the onset of gassing. The time delay resulting therefrom is generally sufficient to allow the driving cells to use up or lose their capacity so that they can no longer supply enough voltage or current to the cell being driven to cause gassing. Accordingly, cell closure failure due to excess gassing is prevented. Accurate adjustments of anode capacity relative to cathode capacity are possible so that complete discharge of the anode will not discharge more than approximately fifty percent of cathodic capacity. Thus, complete exhaustion of the manganese dioxide and resultant irreversible reactions are positively prevented. In addition, this anode composition provides an excellent matrix for redeposition of the zinc upon the charging of the cell. Rechargeable alkaline cells employing these anodes may be discharged to zero volts without sacrificing cycle life.

The use of powdered copper oxide or metallic copper in conjunction with the zinc in a similar manner in addition to providing the above advantages also provides an excellent means for increasing the low temperature conductivity and rechargeable characteristics of the anode. The powdered metallic copper supplied or that formed by the reaction of copper oxide with part of the zinc is not only an excellent electrical conductor but also provides an even better matrix than lead oxide for redeposition of zinc when the cell is recharged. On the other hand, the deep discharge behavior of this composite anode is slightly inferior to that of the lead oxide-zinc anode. If desired, copper powder may be utilized in conjunction with lead oxide, both being mixed with powdered zinc, to combine the superior deep discharge characteristics of the lead oxide with the superior matrix characteristics provided by the copper.

Finally, metallic magnesium may be incorporated in a zinc anode to accomplish the objects of the invention.

DRY CELL
Paul A. Marsal, Rocky River, Karl Kordesch, Lakewood, and Lewis F. Urry, Parma, Ohio, assignors to Union Carbide Corporation, a corporation of New York
Filed Oct. 9, 1957, Ser. No. 689,084
7 Claims. (Cl. 136—107)

This invention relates to primary cells, and more particularly, to dry cells containing an alkaline electrolyte and a depolarizer consisting of manganese dioxide.

The main object of this invention is to provide novel primary cell constructions capable of outperforming conventional Le Clanche-type cells under practically all operating conditions.

A further object of this invention is to provide a cell system having improved characteristics owing to the incorporation therein of means for improving ionic and electronic migration.

A further object of the invention is to provide a cell of the type described, which cell is particularly efficient under heavy continuous drains.

Another object of the present invention is the provision of a novel cell system having flash current and potential maintenance of 80 percent and 95 percent, respectively, after one year of storage.

These and other related objects and advantages of the present invention will become apparent as the description thereof proceeds, particularly when taken in conjunction with the accompanying drawing wherein:

Fig. 1 is a front elevational view, partly in section, of a cell in accordance with the invention;

Fig. 2 is a front elevational view, partly in section, of a cell of the invention, equipped with an electrolyte reservoir;

Fig. 3 is a side view of an electrolyte core suitable for use in the cell of Fig. 2;

Fig. 4 is similar to Figs. 1 and 2, but shows a modification of the invention;

Fig. 5 is a bottom view of the cell of Fig. 3;

Fig. 6 is similar to Figs. 1, 2 and 3, but shows additionally improved venting means for the cell of the invention; and

Fig. 7 is a front elevation, partly in section, of another embodiment of the present invention.

In the above drawings the same reference characters identify the same or like parts.

The cell of the invention consists of an electron producing zinc anode, an ion carrying caustic electrolyte, and a hydroxyl ion-producing manganese dioxide cathode.

The reactions, which are believed to take place in the cell of the invention, simply stated, are as follows:

(1) $Zn \rightarrow Zn^{++} + 2E$ (at anode)
(2) $MnO_2 + H_2O \rightarrow MnO + 2OH^-$ (at cathode)
(3) $Zn^{++} + 2OH^- \rightarrow ZnO + H_2O$ (at anode)

The over-all reaction therefore is:

(4) $Zn + MnO_2 \rightarrow ZnO + MnO$ (both products being considered insoluble).

It has been found that two paths are necessary in order for the system to function; namely, a path for electron flow from the anode to the cathode, and a path for the transfer of hydroxyl ions from the cathode to the anode. (The zinc ions stay by the donor zinc, and so the hydroxyl ions must come to them.)

The cathode or hydroxyl producing portion of this

2

system is manganese dioxide (in Equation 2) which, when it receives electrons and if it is in contact with water, will take on electrons. In the process, the cathode valency is changed, and oxygen ions are liberated, which react with the water present to give negatively charged hydroxyl ions. However, since manganese dioxide is a very poor electron conductor, if electrons are introduced at only one spot on a large chunk, only the material around that contact point comes into the reaction. A very large surface area of the manganese dioxide must be in contact with electrolyte since it is only at this surface area that water is available to enter into the reaction, and a carrier is available to carry off the ions as they are produced. These requirements dictate that the manganese dioxide be available in the form of small particles.

It has been observed that since the cathode is not one large unit which is easily contacted electronically; but is, rather, a composite of very small cathodes, each of these must be linked to the anode by continuous ion and electron paths.

In accordance with the invention, an electron path is provided by mixing in with the manganese dioxide, particles of some inert, electronically conductive fibres or powder such as iron, graphite or carbon in such a way that each particle of manganese dioxide is in contact with a continuous path back to a common electron collector electrode.

The ion path is provided by mixing in with the manganese dioxide and the conductive material some hydroxyl containing electrolyte such as KOH solution. Once again each particle of manganese must be contacted, and a continuous path from each particle to the zinc assured. The various materials which are blended together to form the cathode are called a "mix."

It has been observed also, in accord with the present invention, that the internal electrical resistance of the cell must be kept at a minimum; otherwise, its useful voltage will be depressed and its energy will be expended uselessly in the form of heat. The requirement of very low cathode resistance dictates certain properties in connection with the mix and the manner in which it is prepared and formed. In its loose state, the particle to particle contact of its electron carrying components is poor, and the cumulative contact resistance is high. Tightly packed, the particle contact is improved and the mix resistance becomes low. Additionally, the mix must be firmly packed against an inert electrode, and held there so that at least one cathode contact point is available for external connection.

Typical cells embodying the teachings of this invention are shown with modifications in each of Figs. 1, 2 and 3, and comprise an outer drawn steel can container 1 serving as a cathode current collector; a cathode 2 consisting of manganese dioxide, graphite and electrically conductive filamentary particles such as iron and steel wool, graphite-coated fibers and mixtures of the foregoing. This cathode is disclosed in greater detail, and claimed in the co-pending application of P. A. Marsal, A. Tasch and L. F. Urry, Serial No. 689,085, filed October 9, 1957. Also suitable for use in the cell of the invention are cement-bonded cathodes of the type disclosed and claimed in the co-pending application of K. Kordesch, Serial No. 689,082, filed October 9, 1957.

An ionically-permeable separator, shown at 3, is provided in the cell, in contact with the cathode wall 2. One edge of the separator is folded inward so that when a cardboard disc 10 is placed, an effective seal is provided against the migration of anode or cathode particles. The separator may also comprise two wraps of Viskon-vinyon paper, each about 0.008 inch thick.

Figure 3.129: Karl Kordesch, an Austrian battery expert who was brought to the United States as part of Operation Paperclip, invented alkaline dry batteries in 1957 or earlier.

Es sind schon Brennstoffelemente mit einem sauren Elektrolyten zum Betrieb mit Wasserstoff und Chlorgas bekannt. Es ist ferner bekannt, in solchen Brennstoffelementen mindestens eine rohrförmige Wasserstoffelektrode aus porösem, aktiviertem, kohlenstoffhaltigem Material mit einer Porosität von 30 bis 35%, die als Wasserstoffdissoziationskatalysator eine Edelmetallbeschichtung hat, zu verwenden. Es ist schließlich bekannt, in diesen Brennstoffelementen mindestens eine rohrförmige Chlorelektrode aus porösem, aktiviertem, kohlenstoffhaltigem Material zu verwenden.

Die deutsche Patentschrift 259 241 beschreibt ein Wasserstoff-Chlor-Brennstoffelement mit einer Chlorelektrode aus Kohlenstoff. Nach der britischen Patentschrift 521 773 sind Wasserstoff-Chlor-Brennstoffelemente bekannt, bei denen die Elektrode aus poröser Retortenkohle oder Graphit bestehen können. Beiden Veröffentlichungen läßt sich kein Hinweis darauf entnehmen, daß es möglich ist, die Wirksamkeit der Kohlenstoffelektroden durch Katalysatoren zu verbessern.

Die Erfindung betrifft ein Brennstoffelement mit einem sauren Elektrolyten zum Betrieb mit Wasserstoff und Chlorgas mit mindestens einer rohrförmigen Wasserstoffelektrode aus porösem, aktiviertem, kohlenstoffhaltigem Material mit einer Porosität von 30 bis 35%, die als Wasserstoffdissoziationskatalysator eine Edelmetallbeschichtung hat, ferner mit mindestens einer rohrförmigen Chlorelektrode aus porösem, aktiviertem, kohlenstoffhaltigem Material. Das Brennstoffelement ist dadurch gekennzeichnet, daß beide Elektroden in an sich bekannter Weise mit einem Schwermetallkatalysator aus dem Pyrolyseprodukt eines Gemisches von Kobaltnitrat und Aluminiumnitrat versehen sind und daß die Wasserstoffelektrode eine Edelmetallbeschichtung von 0,25 bis 8 mg/cm^2 Rhodium, Iridium, Ruthenium oder Osmium oder mehrerer dieser Metalle hat.

Bei erfindungsgemäßen Brennstoffelementen ist die wirksame Oberfläche der Wasserstoffelektrode vorteilhaft größer, vorzugsweise um 5 bis 19% größer, als die wirksame Oberfläche der Chlorelektrode.

Die Elektroden für die erfindungsgemäßen Brennstoffelemente können z. B. so hergestellt werden, daß man ein Gemisch aus 100 Gewichtsteilen Petroleumkoks, Kokosnußkohle oder Ruß mit 63 Gewichtsteilen Weichpech oder Phenolformaldehydharz und 3 Gewichtsteilen Heizöl zu Rohren formt und diese Formlinge dann 6 Stunden lang auf 1000° C erhitzt. Die Porosität der so hergestellten Kohlekörper beträgt 18 bis 20%. Beim weiteren Erhitzen der Rohre

2

in einer Atmosphäre von Kohlendioxyd bei 850 bis 950° C steigt die Porosität auf etwa 25%.

Anschließend wird eine 0,1molare wäßrige Lösung von Kobaltnitrat und Aluminiumnitrat aufgebracht und die Elektrodenkörper werden erhitzt, wobei aus den Salzen die Verbindung $CoO \cdot Al_2O_3$ entsteht. Diese Behandlung ist in den USA.-Patentschriften 2 615 932, 2 669 598 beschrieben. Nach diesem bekannten Stand der Technik können an Stelle von Kobaltnitrat auch ein oder mehrere Nitrate anderer Schwermetalle, wie Eisen, Nickel, Mangan, Chrom, Kupfer, Silber, Gold, Plantin, Vanadium, Thorium, Seltene Erden u. dgl. verwendet werden. Ebenso können die Salze an Stelle des Salpetersäurerestes auch Reste anderer oxydierender Säuren, wie salpetrige Säure, Chlorsäure, Oxalsäure, Essigsäure, Ameisensäure u. dgl., enthalten.

Beim Erhitzen der getränkten Elektrodenkörper unter Spinellbildung wird ihre Porosität bis auf 30 bis 35% gesteigert.

An diese Behandlung schließt sich die Beschichtung der Wasserstoffelektrode mit einem Katalysator aus Rhodium, Iridium, Ruthenium oder Osmium an. Man kann z. B. eine 10%ige wäßrige Lösung von Rhodiumtrichlorid in einer solchen Menge aufbringen, daß auf jeden Quadratzentimeter der Oberfläche 0,25 bis 8 mg Metall entfallen. Besonders gute Ergebnisse werden mit einer Beschichtung von etwa 2 mg/cm^2 erhalten. Das Zersetzen der aufgebrachten Metallverbindungen geschieht in üblicher Weise, z. B.

HYDRAZINE FUEL CELL WITH ACRYLIC ACID POLYMER MEMBRANE
Karl Victor Kordesch, Lakewood, Ohio, assignor to Union Carbide Corporation, New York, N.Y.
No Drawing. Filed Oct. 3, 1968, Ser. No. 764,965

U.S. Cl. 136—86 5 Claims

ABSTRACT OF THE DISCLOSURE

Alkali metal salts of ethylene-acrylic acid copolymers are useful as selective, ion permeable membranes for permeable membranes for hydrazine-air fuel cells and permit operation of the cell at high fuel concentrations.

This invention relates to an electrochemical cell which utilizes hydrazine as a fuel. In one aspect, this invention relates to a fuel cell which can operate at high fuel concentrations. In a further aspect, this invention is directed to the use of selective, ion permeable membranes as separators in fuel cells.

Fuel cells which employ hydrazine as a fuel have been known for several years. Such fuel cells generally comprise an anode capable of reacting electrochemically with hydrazine with the production of electric current (hereinafter referred to as a "hydrazine anode"), a cathode to which is supplied the oxidant employed in the fuel cell, an electrolyte in contact with the electrodes, means for supplying oxidant to the cathode and means for supplying hydrazine to the anode. The usual method for supplying hydrazine to the anode is by dissolving the hydrazine in the electrolyte, preferably an aqueous alkaline electrolyte.

Prior art hydrazine anodes typically comprised a porous metal or other porous material which was capable of promoting electrochemical decomposition of hydrazine in contact with the anode, for example, porous nickel or porous Raney nickel. In addition, catalytic materials were often deposited on the porous material, generally metals or compounds of metals from Group VIII of the Periodic Table, for example, the noble metals or heavy metal borides such as nickel boride or cobalt boride.

In practice the hydrazine concentration in the electrolyte must be kept relatively low, i.e., in the range of from about 0.3 to 0.8 percent, otherwise direct chemical attack occurs at the air cathode if it is given no special protection. Hence, hydrazine-air fuel cells are normally provided with a sophisticated fuel injection an monitoring mechanism to periodically supply fresh fuels as it is consumed by the electrochemical reaction and to control the maximum fuel concentration. However, in present methods of monitoring the hydrazine concentration in the electrolyte of a hydrazine fuel cell the total output voltage of the fuel cell battery is monitored and a change in this voltage actuates an electrical switch opening an electromagnetic fuel valve and introducing hydrazine into the electrolyte system. The prime disadvantage of this method is that the net battery voltage invariably includes the cathode potential which tends to vary with time and operating conditions. Also, should there be an over-injection of hydrazine into the system in response to a drop in total battery voltage due, for example, to a slowdown in the electrolyte pumping system or air cooling system, the hydrazine monitoring and injecting system would be unable to recover because of the tendency to inject even more hydrazine to compensate for the decreased voltage, resulting eventually in complete flooding of the system with the hydrazine fuel.

Separate monitoring means for controlling hydrazine concentration which are independent of the main fuel cell

2

battery voltage have also been suggested. However, such separate monitoring devices, have a very low sensitivity because the change in voltage with hydrazine concentration for a single cell is relatively small compared to the total battery voltage.

It would therefore be desirable to have a fuel cell which could operate at relatively high concentrations of hydrazine in the electrolyte, and thus require only occasional fuel injection by means of, for example, a single solenoid valve. However, it has been observed that some means for limiting hydrazine transport from the anode to the cathode compartments is essential when a relatively high concentration of hydrazine is present in the electrolyte. As previously indicated, protection of the air cathode from contact with large amounts of hydrazine is necessary in order to prevent a severe "chemical short" which would not only overpolarize the cathode, but would unnecessarily consume hydrazine fuel and generate considerable heat.

Although cells can operate without a barrier or membrane if the hydrazine concentration is maintained below about 1 percent, the use of concentrations in the 10 to 30 percent range necessitates its use. For instance, in an attempt to operate a fuel cell containing no membrane or other means to restrict hydrazine transport, when an electrolyte containing 10 percent hydrazine was added, very violet gassing occurred and the cell became very hot. In contrast, a similar cell containing the membranes disclosed herein, showed a temperature rise of less than 15° C. during a one and one half hour operating period at a current density of 25 a.s.f.

It is therefore apparent that if no special protection is given to the air cathode, a low hydrazine concentration must be employed and the monitoring means must be highly sophisticated. In the event that the air cathode could be protected from direct chemical reaction, it would be possible to utilize a higher hydrazine concentration, less sophisticated monitoring means and an overall improvement in operation.

Accordingly, one or more of the following objects will be achieved by the practice of this invention. It is an object of this invention to provide a fuel cell which can operate at high fuel concentrations. Another object of this invention is to provide a hydrazine-air fuel cell which can operate at hydrazine concentrations of up to 30 percent in the electrolyte. A further object of this invention is to provide a fuel cell which employs as a separator a selective, ion permeable membrane. A still further object of this invention is to provide a selective, ion permeable membrane which is an alkali-acrylate-acrylic acid-polyethylene copolymer. These and other objects will readily become apparent to those skilled in the art in the light of the teachings herein set forth. In its broad aspect, the invention is directed to a fuel cell comprising, in combination, at least one hydrazine anode, at least one oxidant cathode, current collecting means associated with the anode and cathode, and an electrolyte containing hydrazine, the cathode being separated from the hydrazine in the electrolyte by a selective, ion permeable membrane comprised of alkali metal salts of ethylene-acrylic acid copolymers. Due to the presence of the membrane, relatively high concentrations of hydrazine, i.e., 10 to 30 percent in the electrolyte can be employed and the need for replenishing the fuel at frequent intervals substantially reduced.

As hereinbefore indicated, the selective, ion permeable membranes which are employed in the fuel cells of this invention are alkali metal salts of ethylene-acrylic acid copolymers.

The ethylene-acrylic acid copolymers are prepared by the polymerization of ethylene and acrylic acid (or methacrylic acid) by known techniques described in the liter-

3.7 Film Photography

While early film photography was being developed and practiced in France, the United Kingdom, the United States, and other countries, most of the key technological advances were made in the German-speaking world (Section 3.7.1) and then transferred to other countries (Section 3.7.2).[14] See Figs. 3.131–3.144.

Even the American chemist and chemical historian Aaron Ihde admitted [Ihde 1984, p. 464]:

> The German industry held a virtual monopoly until World War I as a supplier of photographic chemicals, optical glass, and high quality cameras.

3.7.1 Development of Photography

In 1717, Johann Heinrich Schulze (German states, 1687–1744, Fig. 3.132) discovered that light causes some silver solutions to become darker. He used that process to reproduce clear images such as words, although he found that the images in the silver solutions faded with time. Schulze published his results in books that were freely circulated within the European chemical community, thus launching the field of chemical photography.

Building upon Schulze's research, in 1777 Carl Wilhelm Scheele (German states, 1742–1786, Fig. 3.132) developed a chemical fixer for silver solutions to make the light-induced images permanent and to prevent further light from altering the images. Scheele also discovered the need for working with light-sensitive silver solutions in red light until they were fixed. Scheele's research findings, like the earlier discoveries of Schulze, were circulated within the community of European chemists. Thus Schulze and Scheele were responsible for establishing the fundamental chemical and physical principles upon which film photography has been based ever since.

It appears that the German-speaking scientific world reduced the discoveries of Schulze and Scheele to practical and commercial applications by the early nineteenth century. No later than 1839, the brothers Friedrich Wilhelm Enzmann (German states, 1802–1866, Fig. 3.131) and Carl Heinrich Enzmann (German states, 18??–18??) were producing and selling cameras and photographic film as a regular commercial business.

These early German developments in photography spread to other countries, where they were adopted and further publicized by other scientists such as Louis Daguerre (French, 1787–1851) and William Henry Fox Talbot (English, 1800–1877). Especially in the English-speaking world, some historians erroneously assigned credit for the invention of photography to those later scientists, although the original discoveries and inventions clearly arose earlier and in the German-speaking world.

In 1873, Hermann Wilhelm Vogel (German, 1834–1898, not to be confused with the astronomer Hermann Carl Vogel) invented dye color sensitization, which enabled photographic emulsions to be made sensitive to different colors of light, and thereby led to color photography. His results were widely publicized (Fig. 3.133) and became the basis of almost all color photography. *Chronologie Chemie* described Vogel's revolutionary innovation [Neufeldt 2003, p. 74]:

Die Entdeckung der optischen Sensibilisierung photographischer Schichten, so daß diese außer für blau auch für weitere Spektralbereiche lichtempfindlich werden, führt zu naturgetreuen Schattierungen in der Schwarz-Weiß-Photographie. Vogel beobachtet dieses Phänomen zuerst am Farbstoff Korallin, die Weiterentwicklung führt zur Sensibilisierung für grünes und gelbes Licht (orthochromatische Filme) und schließlich mit Hilfe der Polymethin-Farbstoffe zur Sensibilisierung für den gesamten sichtbaren Spektralbereich (panchromatische Filme).	The discovery of optical sensitization of photographic layers, so that they become light-sensitive to other spectral ranges in addition to blue, led to lifelike shading in black-and-white photography. Vogel first observed this phenomenon with the dye coralline; further development led to sensitization for green and yellow light (orthochromatic films) and finally, with the help of polymethine dyes, to sensitization for the entire visible spectral range (panchromatic films).

Ferdinand Hurter (Swiss, 1844–1898, Fig. 3.131) worked to make photography more rigorously systematic, such as defining and measuring film speed, optical density, and other properties.

As shown in Fig. 3.134, Ottomar Anschütz (German, 1846–1907) invented high-speed camera shutters in 1881 and compact portable cameras in 1896.

Momme Andresen (German/Danish, 1857–1951) invented new and improved chemical developers and fixers for photography from the 1880s onward. He helped to build what became known as the Agfa photography company (derived and rebranded from the earlier Aktiengesellschaft für Anilinfabrikation) and employed other chemists such as Ernst Leupold (German, 18??–19??). See Fig. 3.135.

As shown in Fig. 3.136, the brothers Max Skladanowsky (German, 1863–1939) and Emil Skladanowsky (German, 1866–1945) created the Bioscop motion picture camera and projector in 1892 and presented the first public films in 1895.

Adolf Miethe (German, 1862–1927) produced high-quality color photographs using a three-color process beginning in 1901 (Fig. 3.137). He also invented the first practical flash powder for photography.

Raphael Eduard Liesegang (German, 1869–1947, Fig. 3.132) conducted numerous experimental and theoretical analyses of the photochemistry of both black-and-white photography and color photography.

Rudolf Fischer (German, 1881–1957) invented Agfa color film in 1911 (Fig. 3.138). He worked closely with Wilhelm Siegrist (German, 1881–19??) for part of that period.

In 1913, Oskar Barnack (German, 1879–1936) invented the first modern 35 mm still camera, which later was dubbed Leica (for Leitz Camera); see Fig. 3.139. The *Encyclopedia Britannica* described his invention [EB 2010]:

> [D]esigner of the first precision miniature camera to become available commercially, the Leica I, which was introduced in 1924 by the Ernst Leitz optical firm at Wetzlar, Ger.
>
> Barnack was a master mechanic and inventor who joined the Leitz optical firm in 1911. Barnack had completed a prototype of the Leica by 1913, but World War I and the postwar chaos in Germany delayed production. The success of the Leica I promoted the use of 35-millimetre and other small cameras. Barnack determined the standard 24 × 36-millimetre picture size for 35-millimetre film and was partly responsible for the Leitz Elmar lens.

As shown in Fig. 3.140, Max Hagedorn (German, 18??–19??) created improved film stock from 1924 onward.

Ernst Bauer (German, 18??–19??), Wilhelm Schneider (German, 18??–19??), and Gustav Wilmanns (German, 18??–19??) invented Agfa Neu improved color film in 1935. Their technology was showcased in films such as *Frauen sind doch bessere Diplomaten* (Fig. 3.141) and became the basis for most color film around the world after World War II.

Joseph Joshua Weiss (Austrian, 1905–1972, Fig. 3.132) carried out a series of analyses on the photochemical reaction mechanisms in photographic film.

Artur Fischer (German, 1919–2016, Fig. 3.131) invented a system for synchronizing a photo flash with the camera shutter.

The German-speaking world also developed very high-quality optical components and optical devices that were important for photography (p. 680 and Section 6.9).

3.7.2 Transfer of Photography-Related Technologies

As illustrated by the examples above, a wide variety of advanced technologies, components, and methods for photography were created in the German-speaking world. Some were transferred to other countries via patents, publications, and commerce before World War II, but many of the most advanced photographic technologies were only transferred after the war. For some examples of transferred technologies, see Figs. 3.142–3.144 and the following reports:

Scientists from the German-speaking world also developed technologies for electronic photography and transferred those technologies to other countries, especially after World War II. See Sections 6.3, 6.5, and 6.6. Over the course of several decades after World War II, German-derived chemical film technologies for photography were slowly and ultimately almost completely eclipsed by German-derived electronic photography technologies.

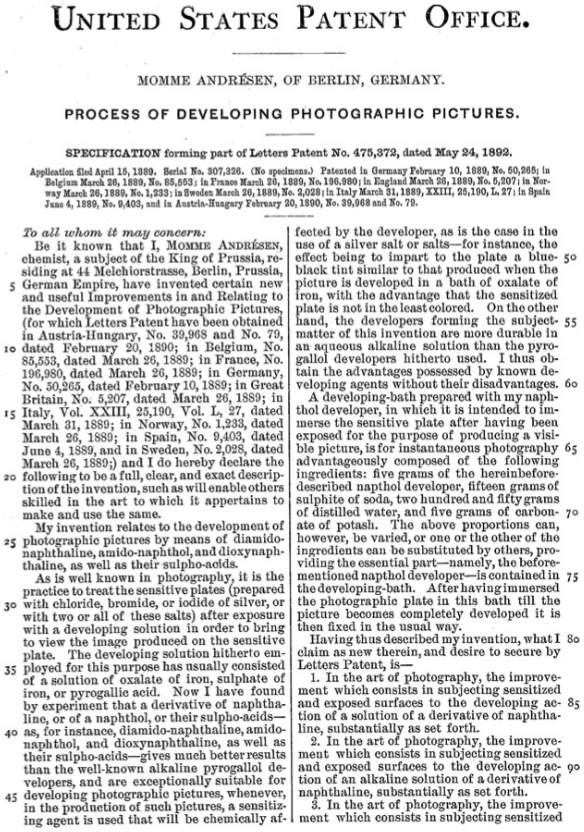
Ernst Leupold (18??–19??)

Chemical developers and fixers for photography



UNITED STATES PATENT OFFICE.

MOMME ANDRÉSEN, OF BERLIN, GERMANY.

PROCESS OF DEVELOPING PHOTOGRAPHIC PICTURES.

SPECIFICATION forming part of Letters Patent No. 475,372, dated May 24, 1892.

Application filed April 15, 1889. Serial No. 307,326. (No specimens.) Patented in Germany February 10, 1889, No. 50,265; in Belgium March 26, 1889, No. 85,553; in France March 26, 1889, No. 196,980; in England March 26, 1889, No. 5,207; in Norway March 26, 1889, No. 1,233; in Sweden March 26, 1889, No. 2,028; in Italy March 31, 1889, XXIII, 25,190, L, 27; in Spain June 4, 1889, No. 9,403, and in Austria-Hungary February 20, 1890, No. 39,968 and No. 79.

To all whom it may concern:

Be it known that I, MOMME ANDRÉSEN, chemist, a subject of the King of Prussia, residing at 44 Melchiorstrasse, Berlin, Prussia, German Empire, have invented certain new and useful Improvements in and Relating to the Development of Photographic Pictures, (for which Letters Patent have been obtained in Austria-Hungary, No. 39,968 and No. 79, dated February 20, 1890; in Belgium, No. 85,553, dated March 26, 1889; in France, No. 196,980, dated March 26, 1889; in Germany, No. 50,265, dated February 10, 1889; in Great Britain, No. 5,207, dated March 26, 1889; in Italy, Vol. XXIII, 25,190, Vol. L, 27, dated March 31, 1889; in Norway, No. 1,233, dated March 26, 1889; in Spain, No. 9,403, dated June 4, 1889, and in Sweden, No. 2,028, dated March 26, 1889;) and I do hereby declare the following to be a full, clear, and exact description of the invention, such as will enable others skilled in the art to which it appertains to make and use the same.

My invention relates to the development of photographic pictures by means of diamido-naphthaline, amido-naphthol, and dioxynaphthaline, as well as their sulpho-acids.

As is well known in photography, it is the practice to treat the sensitive plates (prepared with chloride, bromide, or iodide of silver, or with two or all of these salts) after exposure with a developing solution in order to bring to view the image produced on the sensitive plate. The developing solution hitherto employed for this purpose has usually consisted of a solution of oxalate of iron, sulphate of iron, or pyrogallic acid. Now I have found by experiment that a derivative of naphthaline, or of a naphthol, or their sulpho-acids—as, for instance, diamido-naphthaline, amido-naphthol, and dioxynaphthaline, as well as their sulpho-acids—gives much better results than the well-known alkaline pyrogallol developers, and are exceptionally suitable for developing photographic pictures, whenever, in the production of such pictures, a sensitizing agent is used that will be chemically affected by the developer, as is the case in the use of a silver salt or salts—for instance, the effect being to impart to the plate a blue-black tint similar to that produced when the picture is developed in a bath of oxalate of iron, with the advantage that the sensitized plate is not in the least colored. On the other hand, the developers forming the subject-matter of this invention are more durable in an aqueous alkaline solution than the pyrogallol developers hitherto used. I thus obtain the advantages possessed by known developing agents without their disadvantages.

A developing-bath prepared with my naphthol developer, in which it is intended to immerse the sensitive plate after having been exposed for the purpose of producing a visible picture, is for instantaneous photography advantageously composed of the following ingredients: five grams of the hereinbefore-described napthol developer, fifteen grams of sulphite of soda, two hundred and fifty grams of distilled water, and five grams of carbonate of potash. The above proportions can, however, be varied, or one or the other of the ingredients can be substituted by others, providing the essential part—namely, the before-mentioned napthol developer—is contained in the developing-bath. After having immersed the photographic plate in this bath till the picture becomes completely developed it is then fixed in the usual way.

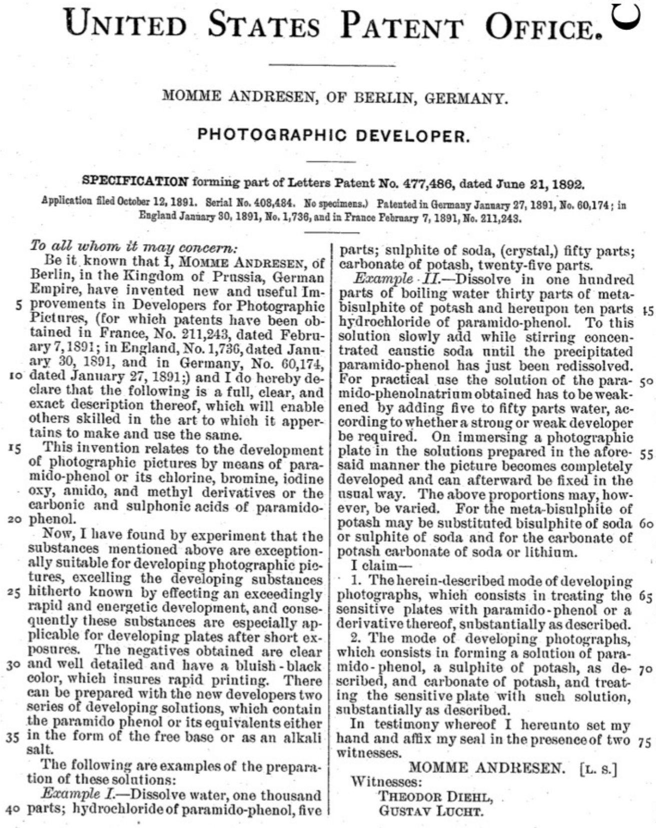
Having thus described my invention, what I claim as new therein, and desire to secure by Letters Patent, is—

1. In the art of photography, the improvement which consists in subjecting sensitized and exposed surfaces to the developing action of a solution of a derivative of naphthaline, substantially as set forth.

2. In the art of photography, the improvement which consists in subjecting sensitized and exposed surfaces to the developing action of an alkaline solution of a derivative of naphthaline, substantially as set forth.

3. In the art of photography, the improvement which consists in subjecting sensitized

---



UNITED STATES PATENT OFFICE.

MOMME ANDRESEN, OF BERLIN, GERMANY.

PHOTOGRAPHIC DEVELOPER.

SPECIFICATION forming part of Letters Patent No. 477,486, dated June 21, 1892.

Application filed October 12, 1891. Serial No. 408,484. No specimens.) Patented in Germany January 27, 1891, No. 60,174; in England January 30, 1891, No. 1,736, and in France February 7, 1891, No. 211,243.

To all whom it may concern:

Be it known that I, MOMME ANDRESEN, of Berlin, in the Kingdom of Prussia, German Empire, have invented new and useful Improvements in Developers for Photographic Pictures, (for which patents have been obtained in France, No. 211,243, dated February 7, 1891; in England, No. 1,736, dated January 30, 1891, and in Germany, No. 60,174, dated January 27, 1891;) and I do hereby declare that the following is a full, clear, and exact description thereof, which will enable others skilled in the art to which it appertains to make and use the same.

This invention relates to the development of photographic pictures by means of paramido-phenol or its chlorine, bromine, iodine oxy, amido, and methyl derivatives or the carbonic and sulphonic acids of paramido-phenol.

Now, I have found by experiment that the substances mentioned above are exceptionally suitable for developing photographic pictures, excelling the developing substances hitherto known by effecting an exceedingly rapid and energetic development, and consequently these substances are especially applicable for developing plates after short exposures. The negatives obtained are clear and well detailed and have a bluish-black color, which insures rapid printing. There can be prepared with the new developers two series of developing solutions, which contain the paramido phenol or its equivalents either in the form of the free base or as an alkali salt.

The following are examples of the preparation of these solutions:

Example I.—Dissolve water, one thousand parts; hydrochloride of paramido-phenol, five parts; sulphite of soda, (crystal,) fifty parts; carbonate of potash, twenty-five parts.

Example II.—Dissolve in one hundred parts of boiling water thirty parts of meta-bisulphite of potash and hereupon ten parts hydrochloride of paramido-phenol. To this solution slowly add while stirring concentrated caustic soda until the precipitated paramido-phenol has just been redissolved. For practical use the solution of the paramido-phenolnatrium obtained has to be weakened by adding five to fifty parts water, according to whether a strong or weak developer be required. On immersing a photographic plate in the solutions prepared in the aforesaid manner the picture becomes completely developed and can afterward be fixed in the usual way. The above proportions may, however, be varied. For the meta-bisulphite of potash may be substituted bisulphite of soda or sulphite of soda and for the carbonate of potash carbonate of soda or lithium.

I claim—

1. The herein-described mode of developing photographs, which consists in treating the sensitive plates with paramido-phenol or a derivative thereof, substantially as described.

2. The mode of developing photographs, which consists in forming a solution of paramido-phenol, a sulphite of potash, as described, and carbonate of potash, and treating the sensitive plate with such solution, substantially as described.

In testimony whereof I hereunto set my hand and affix my seal in the presence of two witnesses.

MOMME ANDRESEN. [L. S.]

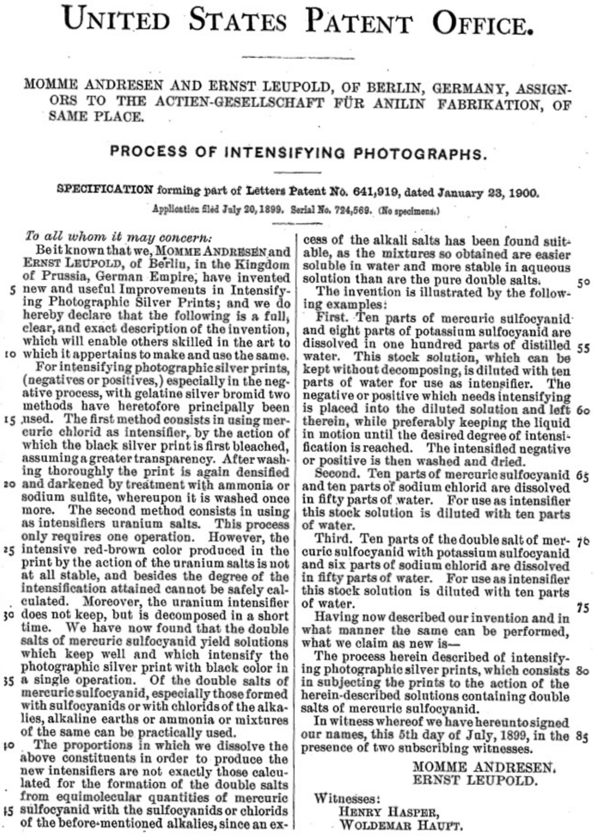
GUSTAV LUCHT.



UNITED STATES PATENT OFFICE.

MOMME ANDRESEN AND ERNST LEUPOLD, OF BERLIN, GERMANY, ASSIGNORS TO THE ACTIEN-GESELLSCHAFT FÜR ANILIN FABRIKATION, OF SAME PLACE.

PROCESS OF INTENSIFYING PHOTOGRAPHS.

SPECIFICATION forming part of Letters Patent No. 641,919, dated January 23, 1900.

Application filed July 20, 1899. Serial No. 724,569. (No specimens.)

To all whom it may concern:

Be it known that we, MOMME ANDRESEN and ERNST LEUPOLD, of Berlin, in the Kingdom of Prussia, German Empire, have invented new and useful Improvements in Intensifying Photographic Silver Prints; and we do hereby declare that the following is a full, clear, and exact description of the invention, which will enable others skilled in the art to which it appertains to make and use the same.

For intensifying photographic silver prints, (negatives or positives,) especially in the negative process, with gelatine silver bromid two methods have heretofore principally been used. The first method consists in using mercuric chlorid as intensifier, by the action of which the black silver print is first bleached, assuming a greater transparency. After washing thoroughly the print is again densified and darkened by treatment with ammonia or sodium sulfite, whereupon it is washed once more. The second method consists in using as intensifiers uranium salts. This process only requires one operation. However, the intensive red-brown color produced in the print by the action of the uranium salts is not at all stable, and besides the degree of the intensification attained cannot be safely calculated. Moreover, the uranium intensifier does not keep, but is decomposed in a short time. We have now found that the double salts of mercuric sulfocyanid yield solutions which keep well and which intensify the photographic silver print with black color in a single operation. Of the double salts of mercuric sulfocyanid, especially those formed with sulfocyanids or with chlorids of the alkalies, alkaline earths or ammonia or mixtures of the same can be practically used.

The proportions in which we dissolve the above constituents in order to produce the new intensifiers are not exactly those calculated for the formation of the double salts from equimolecular quantities of mercuric sulfocyanid with the sulfocyanids or chlorids of the before-mentioned alkalies, since an excess of the alkali salts has been found suitable, as the mixtures so obtained are easier soluble in water and more stable in aqueous solution than are the pure double salts.

The invention is illustrated by the following examples:

First. Ten parts of mercuric sulfocyanid and eight parts of potassium sulfocyanid are dissolved in one hundred parts of distilled water. This stock solution, which can be kept without decomposing, is diluted with ten parts of water for use as intensifier. The negative or positive which needs intensifying is placed into the diluted solution and left therein, while preferably keeping the liquid in motion until the desired degree of intensification is reached. The intensified negative or positive is then washed and dried.

Second. Ten parts of mercuric sulfocyanid and ten parts of sodium chlorid are dissolved in fifty parts of water. For use as intensifier this stock solution is diluted with ten parts of water.

Third. Ten parts of the double salt of mercuric sulfocyanid with potassium sulfocyanid and six parts of sodium chlorid are dissolved in fifty parts of water. For use as intensifier this stock solution is diluted with ten parts of water.

Having now described our invention and in what manner the same can be performed, what we claim as new is—

The process herein described of intensifying photographic silver prints, which consists in subjecting the prints to the action of the herein-described solutions containing double salts of mercuric sulfocyanid.

In witness whereof we have hereunto signed our names, this 5th day of July, 1899, in the presence of two subscribing witnesses.

PATENTSCHRIFT

— № 257160 —

KLASSE 57*b*. GRUPPE 18.

NEUE PHOTOGRAPHISCHE GESELLSCHAFT AKT.-GES.
IN BERLIN-STEGLITZ.

Verfahren zur Herstellung von Farbenphotographien.

Patentiert im Deutschen Reiche vom 14. Juni 1911 ab.

Es ist bekannt, daß man durch Baden von belichteten Halogensilberschichten in geeigneten Lösungen unmittelbar einfarbige Bilder erhalten kann, indem das belichtete Halogensilber den in den Lösungen vorhandenen Stoff zu einem unlöslichen Farbstoff oxydiert, der sich auf dem reduzierten Silber niederschlägt. In der Folge soll diese Art der Entwicklung als »farbige Entwicklung« und die dieselbe verursachenden Stoffe als »Farbbildner« bezeichnet werden.

Das vorliegende Verfahren benutzt diese stärkere Oxydationsfähigkeit von belichtetem Halogensilber gegenüber unbelichtetem zur Erzeugung von Farbenphotographien. Diese ist auf verschiedene Arten möglich, und zwar können ebenso gut additive als auch subtraktive Farbenbilder hergestellt werden.

I. Soll z. B. ein Farbraster als ein additives Farbbild hergestellt werden, so belichtet man eine lichtempfindliche Halogensilberschicht unter einem Raster, der zu etwa einem Drittel seiner Fläche lichtdurchlässig und zu zwei Dritteln gedeckt ist, badet die Schicht dann in einer einen blauen Farbstoff erzeugenden Lösung, z. B. Indoxyl, kopiert unter einem zweiten Raster so, daß wiederum ein Drittel der Fläche belichtet wird, und badet in einer einen roten Farbstoff erzeugenden Lösung, z. B. Thioindoxyl. Man belichtet dann die ganze Fläche ohne das Rasternegativ; dabei wird der Rest, also das bisher unbelichtete Halogensilber, beeinflußt, das sich nunmehr beim Baden in einer einen grünen Farbstoff ergebenden Lösung, z. B. Chlorindoxyl, grün färbt. Bei der zweiten und dritten Belichtung schützt das unter den Farbkörpern liegende Silber das unter diesem liegende unveränderte Halogensilber vor weiterer Belichtung und Entwicklung. Dieser Schutz kann außerdem schon durch den erzeugten Farbstoff hervorgerufen werden, wenn man bei den späteren Belichtungen solches Licht anwendet, das durch den bereits erzeugten Farbstoff absorbiert wird. Das so hergestellte dreifarbige Bild (Raster) kann nach Entfernung des unter den Farbkörpern liegenden Silbers, z. B. mit Farmerschem Abschwächer, und nach Entfernung des nicht veränderten Halogensilbers mittels eines Fixiermittels als Dreifarbenraster dienen.

II. Für subtraktive Bilder werden, wie üblich, drei Teilnegative verwendet, deren jedes einer der Grundfarben entspricht. Hiervon werden auf Halogensilberschichten drei Teilpositive kopiert und diese in der oben angegebenen Weise in den entsprechenden Farbbildnern entwickelt und alsdann übereinander gelegt.

Die Teilpositive kann man auch direkt aus einem mittels Raster hergestellten komplementärfarbigen Negativ erhalten, indem man von

DR. RUDOLF FISCHER IN BERLIN-STEGLITZ.

Verfahren zur Herstellung farbiger photographischer Bilder.

Patentiert im Deutschen Reiche vom 7. Februar 1912 ab.

Die Entwicklung photographischer Halogensilberschichten führt im allgemeinen zu einem schwarzen Bilde, das im wesentlichen aus Silber besteht. Jedoch sind vereinzelte Fälle bekannt, in denen man direkt beim Entwickeln gefärbte Bilder erhalten kann. So ergibt die Entwicklung mit Pyrogallol ein gelbbraunes Bild, mit Indoxyl ein blaues, mit Thioindoxyl ein rotes Bild. Auch die anderen gebräuchlichen photographischen Entwickler geben unter geeigneten Bedingungen (Abwesenheit von Natriumsulfit und ähnlichen Körpern) mehr oder weniger gefärbte Bilder. Die so erzielten Färbungen sind jedoch entweder nicht sehr markant, oder wie bei den Entwicklern aus der Indigogruppe nicht leicht zu erhalten. Es wurde nun gefunden, daß man zu außerordentlich stark farbigen Bildern auf eine sehr leichte Weise gelangen kann, indem man nicht die Oxydationsprodukte der Entwickler allein benutzt, sondern zu den Entwicklern Stoffe hinzufügt, die sich mit den beim Entwickeln entstehenden Oxydationsprodukten des Entwicklers zu schwer löslichen gefärbten Körpern kuppeln. Je nach den angewandten Entwicklern oder Kupplungskörpern erhält man Vertreter verschiedener Farbstoffklassen, von denen folgende als Beispiele angeführt seien:

p-Amidophenole + Phenole = Indophenole,
p-Phenylendiamine + Phenole = Indoaniline und Oxazime,
p-Phenylendiamine + Amine = Indamine,
p-Phenylendiamine + Thiophenole = Indothiophenole,

$$\left.\begin{array}{l}\text{p-Amidophenole}\\ \text{p-Phenylendiamine}\end{array}\right\} + \left\{\begin{array}{c}\text{Verbindungen, die saure Methylen-}\\ \text{verbindungen enthalten}\end{array}\right\} = \text{Azomethine.}$$

Die am schwersten löslichen Körper erhält man mit p-Phenylendiamin als Entwickler und Phenolen oder Verbindungen mit sauren Methylengruppen als Kupplungskörper.

Die p-Phenylendiamine umfassen hierbei auch die Seitenketten- und Kernhomologen, die in der Amidogruppe oder im Kern substituierten Verbindungen des p-Phenylendiamins.

Beispiele: p-Phenylendiamin, p-Toluylendiamin, Amido-p-Phenylendiamin, Chlor-p-Phenylendiamin, Monoäthyl-p-Phenylendiamin, Dimethyl-p-Phenylendiamin.

Ferner kann die Amidogruppe auch in ein Ringsystem eingeschlossen sein: p-Aminophenylenpiperidin.

Unter Phenolen sind ebenfalls die Seitenketten- und Kernhomologen und die Substitutionsprodukte zu verstehen.

Beispiele: Phenol, Kresol, Naphtol, o-Amidophenol, Trichlornaphtol, Resorcinmethyläther, Naphtolsulfosäure.

Die sauren Methylenverbindungen können sowohl aliphatischer als auch aromatischer Natur sein.

UNITED STATES PATENT OFFICE.

MAX HAGEDORN, OF DESSAU IN ANHALT, AND WERNER GLADHORN, OF DESSAU-ZIEBIGK, GERMANY, ASSIGNORS TO ACTIEN GESELLSCHAFT FÜR ANILIN FABRIKATION, OF BERLIN.

PHOTOGRAPHIC FILM.

Application filed May 15, 1925, Serial No. 30,622, and in Germany December 23, 1924.

This invention relates to photographic films for projection purposes.

Heretofore it was the practice to coat the rear surface of the films with a fatty substance, to facilitate the gliding or slipping thereof in a projection apparatus. The superficially applied substance has the disadvantage that it can be easily wiped off, and for this reason soils the film and the apparatus.

The present invention has for its object the provision of a readily slipping film without the disadvantages mentioned.

Briefly expressed, the invention consists in incorporating the substance producing the slipping effect in the surface layer of the film instead of applying it upon the surface thereof. In this way the substance can be no longer wiped off, so that a transfer to other parts of the film or to the apparatus is avoided, and a uniform and permanent slipping effect is obtained. Another advantage of the invention is the possibility of imparting the slipping quality during the manufacture of the film carrier body in wide strips, while up to now the treatment was applied only to the narrow finished picture strips.

Another material advantage of the invention lies in the possibility of using substances which as such have no slipping quality, which however when incorporated in a state of fine subdivision in the surface layer of the film, produce a marked slipping effect.

The invention may be carried out by dissolving the substance to be applied in a suitable solvent which has a solvent action upon the mass of the film and then applying the solution to the surface of the film in well known manner, as for instance by a brush, by spraying or by drawing the film through the solution.

It is also possible to apply substances which are practically insoluble in the solvent. They are mixed with the latter, in a state of fine subdivision, and then penetrate under the action of the solvent upon the film into the surface thereof. Particularly applicable in this respect are colloidal suspensions of substances such as gypsum, zinc carbonate or other material which does not chemically react upon the celluloid material or generally of white pigments, which become so finely distributed in the surface layer of the film that the transparency thereof is not materially affected.

The following examples may be considered as fairly representing the invention:

1. A 1–1.5% solution of sodium stearate in methanol is applied in any suitable manner. The solvent, by its action upon the film, makes it possible for the sodium stearate to penetrate into the latter. After evaporation of the solvent, as for instance caused methodically by movement of the film in a warm air current, the sodium stearate is deposited in the surface of the film.

2. A colloidal suspension of gypsum in menthanol is prepared in a well known manner, so that the percentage of gypsum is about .1%. The suspension is applied in the same manner as before indicated. The solid particles embed themselves in the surface of the film body and form an integral part thereof.

These two examples, it is understood, are merely representatives of relatively large classes of soluble and insoluble substances available for carrying out the object of the invention. Similarly, methanol is referred to merely as a well known solvent for films. Any other solvent known or unknown at present may be used in a like manner. The film body may be treated during the manufacture as previously suggested or after the film is finished. In the latter case the face opposite the sensitive layer is treated, as is understood.

In the drawing forming a part of this specification, 2 represents the body of a celluloid film serving as the usual support for the photo-sensitive gelatine layer 1. In the surface opposite the photo-sensitive layer 1, is embedded finely divided material of the order of gypsum, zinc carbonate or generally of the order of white pigments, which when finely distributed over the entire surface does not materially affect the transparency thereof, or conversely expressed, which has light-transmitting quality. The material which may be carried into the body of the film to any practical desirable extent defines a zone 3 co-extensive with the film. While there is considerable latitude in regard to the method of embedding the material in

MAX HAGEDORN, OF DESSAU IN ANHALT, GERMANY, ASSIGNOR, BY MESNE ASSIGNMENTS, TO AGFA ANSCO CORPORATION, OF BINGHAMTON, NEW YORK, A CORPORATION OF NEW YORK

PROTECTIVE LAYER ON PHOTOGRAPHIC FILMS

Application filed April 25, 1927, Serial No. 186,567, and in Germany May 1, 1926.

One applies a protective layer to the back surface of a photographic film for several purposes; for instance for preventing the film from rolling up during development, fixing and drying, for making the film less liable to damage, making it softer and better adapted to slide, which is of particular importance in the cinematograph film; for protecting the film against electric discharges which are liable to occur owing to the electrical excitation of the film, it may be by movements in the cinematograph apparatus, for minimizing the alteration in length and breadth of the film owing to the effect of atmospheric moisture.

For these purposes protective layers of various kinds have been suggested, for example varnishes, resins, gelatin, individual cellulose esters and ethers, either alone or with addition of electrolytes, substances which are hygroscopic or diminish the surface tension or friction of the film. Another proposition has been that the back surface of the emulsion carrier should be varied in its composition by treating it with solvents, with or without the addition of electrolytes or substances which are hygroscopic or diminish the surface tension or the friction of the surface.

In order to lend to the protective layer the properties desired for the particular purposes, the layer has been made up of advantageously mixed substances which are more or less foreign to the emulsion carrier.

As contrasted with this practice a protective layer which does not consist of a mixture but is a chemical individual compound of the properties required for the purpose would be a technical advance.

The present invention consists of a protective layer made of cellulose derivatives other than nitroacetate soluble in organic solvents and containing several different radicles as substituents, particularly radicles of more than one acid or besides ether groups radicles of acids. Such compounds may be obtained from cellulose derivates having still esterifiable hydroxyl groups, particularly from mono-esters, di-esters, mono-ethers, di-ethers or mixtures of such compounds, swollen or dissolved in organic solvents by treating them, preferably in the presence of a substance promoting the esterification, with functional derivatives of inorganic or organic acids, for instance their esters, chlorides, amides, anhydrides or mixed anhydrides.

According to the desired effect a suitable cellulose derivative of the indicated kind is selected for the particular case, which presents no difficulty, since a large number of these compounds having correspondingly different properties are available. For example, if a film having a high capacity for sliding and small shrinkage is required there may be used cellulose-acetate-stearate as protective layer. The same effect has a protective layer made from cellulose-ethyl-ether-stearate. When protection against electric discharges is in question the layer may consist of cellulose-ether-phosphate or cellulose-acetate-phosphate.

In carrying out the invention a solution of the said cellulose derivates containing several different radicles as substituents is applied to the photographic film, particularly to the back surface of such a film.

The following examples illustrate the invention without limiting it:

Example 1.—60 grams of cellulose-acetate-phosphate are dissolved in 3750 cc. of acetone and 1600 cc. of water, with addition of 300 cc. of glycol - mono - methyl - ether - acetate. The layer produced by applying this solution in the known manner to the back surface of the film imparts good protection against electric discharge.

Example 2.—For producing a protective layer on the back surface of the film there is used a 1 per cent solution of cellulose-ethyl-ether-stearate or cellulose-acetate-stearate in a mixture of 1 part of alcohol, 3 parts of benzene and 2 parts of acetone. This layer greatly diminishes the resistance of the film to sliding in the cinematograph apparatus.

The aforesaid solutions may contain still other additions remaining in the dry layer.

The accompanying drawing shows on an enlarged scale in section a film provided with a protective layer according to the present

No Drawing. Application August 14, 1933, Serial No. 685,147. In Germany August 10, 1932

11 Claims. (Cl. 95—7)

Our present invention relates to a photographic material and more particularly to a light sensitive material which is adapted for the most various purposes occurring in photography.

One of its objects is to provide a process for the manufacture of light sensitive layers. Another object is the new light sensitive layers. Further objects will be seen from the detailed specification following hereafter.

We have found that polyacrylic acid and the salts thereof or other polymeric carboxylic acids and the mixed polymerization products of these acids and their salts are well suited to be used instead of, for instance, gelatin for the preparation of photographic layers of all kinds. Such polymeric acids are, for instance, polymethylene-malonic acid, polymaleic acid, the polymerization product from a mixture of styrol and acrylic acid, from a mixture of acrylic acid nitrile and acrylic acid, from a mixture of acrylic acid nitrile, acrylic acid ethyl ester and acrylic acid, from a mixture of styrol and maleic acid, or a mixture from vinylmethylether and methylene maleic acid. The salts of these acids which enter into consideration for the purpose of the invention are the inorganic and organic salts, for instance, the sodium salt, the potassium salt, the lead salt, the mercury salt, or the salt obtainable by the reaction between triethanolamine and the required acid. As to the degree of polymerization of the product, care should be taken that it is not too high, since the product would then lose its capacity of swelling in water which is indispensable for photographic layers. Therefore the polymerization should not proceed farther than to a k-value of about 110 (cf. Cellulose Chemie 1932, pages 60 to 61).

The material is made into photographic layers in a manner analogous to that according to which gelatin is worked up for this purpose and which will be more clearly seen from the examples. The material is dissolved in water if required by the addition of ammonia and the light-sensitve material incorporated therein. The solution thus prepared is cast on a support and dried. If required our new binding agent may be used in admixture with other binding agents, for instance, gelatin, casein and the like. Asra support there may be used a glass plate, a metal plate, a film made of a cellulose derivative, paper, a web and the like. However, there may also be prepared light sensitive sheets without any carrier in the manner known in the art. The light sensitive component can also be incorporated in the finished sheets by imbibition. The casting solution is preferably given a viscosity equal to that of a usual gelatin solution of 4 to 5 per cent strength. The viscosity may be regulated by suitably selecting the concentration of the casting solution.

The nature of the binding material for the light sensitive substances permits variation of the mechanical properties of the light sensitive layers within wide limits and improvement of such layers as compared with gelatin layers. The said nature also permits application of quite a number of methods for the after-treatment of the finished light sensitive layers. Thus, for instance, the layers may be hardened not only by the well known treatment with formaldehyde or with chromic alum, but also, if the polymeric substance is a free acid, by formation of a suitable salt from the acid, the effect being different in respect of the solubility and the surface hardness of the layér. In a similar way the formation of salts permits change to a large extent of the sensitiveness of the surface towards pressure or mechanical deterioration as well as the hydrophile character and the smoothness of the surface. Furthermore it is possible, by the formation of dyestuff salts, for instance, with methylene blue, to modify the transparency of the layer for rays of various wave lengths.

When exposing the layer under a suitable negative, for instance, a half-tone or a screen negative, the binding agent is hardened in a relief-like gradation, so that the layer, by means of cold or warm water, may be developed into a swelling or wash-out relief.

If desired the developed relief may subsequently be hardened by means of a solution of calcium or magnesium salts, whereby the binding agent is transformed into the water-insoluble calcium or magnesium salt of the polycarboxylic acid.

The relief produced in the manner described may directly be used, in the same way as a corresponding gelatin relief, for an etching resist or as a flat printing form or a relief printing form, or for the preparation of a printing block by moulding a relief.

The following examples illustrate the invention:

Example 1.—5 cc. of an aqueous solution of 8 per cent strength of polyacrylic acid are mixed with 4 cc. of a solution of potassium bichromate of 10 per cent strength which has been neutralized with ammonia and diluted with 20 cc. of water. The solution is applied on to a zinc plate, the surplus of solution is removed by centrifuging, and after drying the plate is exposed under a

No Drawing. Application March 2, 1934, Serial No. 713,771. In Germany March 4, 1933

4 Claims. (Cl. 106—40)

Our present invention relates to the manufacture of film.

One of its objects is to provide a process for the manufacture of film having improved mechanical properties. Another object is the improved film. Further objects will be seen from the detailed specification following hereafter.

According to this invention it has been found that compounds having no dissolving action on cellulose esters and which are derived from the paraffins and the high boiling carbon hydrates available in nature, are particularly suited as softening agents for organic cellulose esters and mixed organic and inorganic cellulose esters, for instance, cellulose acetate, cellulose nitroacetate, and cellulose acetobutyrate. The softening agents according to this invention are the esters of monovalent alcohols with fatty acids or the alcohols which are obtainable by oxidation of the above mentioned paraffins and high boiling hydrocarbons, such as are resulting in the hydrogenation under pressure of coal or brown coal, or in cracking the hydrocarbons contained in the high boiling fractions. In view of the heterogeneity of the starting material, the fatty acids or the alcohols are obtained in form of mixtures which may differ in accordance with different oxidizing processes. They contain nearly all arborescent carbon chains and therefore differ principally from the natural fatty acids or the alcohols obtainable from the fatty acids by reduction. If the esters shall be suitable for the manufacture of supports for photographic layers they must not contain strongly smelling compounds. For the purposes of the invention there are particularly suited the esters which are derived from fatty acids having an unbranched chain of at least 8 carbon atoms or the alcohols having an unbranched chain of at least 8 carbon atoms. The lower esters or alcohols are not so useful because they have a high vapor pressure and therefore are very volatile. The softening agents prepared by oxidizing paraffins such as lignite wax and ozocerite, or the high-boiling brown coal oils by means of air (with or without a catalyzer), nitric acid or chromic acid are preferred without limiting the invention.

The following examples serve to illustrate the invention:

Example 1.—Acetylcellulose containing 56 per cent. of acetic acid is dissolved in a mixture of methylene chloride, chloroform and amyl alcohol in the proportions of 2:5:2 to a solution of 18 per cent strength while adding 20 per cent of the alcohols obtained by oxidizing commercial paraffin. The solution obtained is cast to form a film of 0.135 mm. thickness. This film shows the following data in comparison with a film prepared with triphenylphosphate, the usual softener for acetylcellulose.

Kind of addition	Breaking load, kilo	Elongation, percent	Creasing number
20 per cent of alcohols obtained by oxidizing commercial paraffin	88	42	335
20 per cent of triphenyl-phosphate	89	37	191

Example 2.—To a solution of 180 grams of cellulose acetobutyrate in 820 grams of a mixture of acetone and alcohol in the ratio 8:2 there are added 36 grams of the butylester of the mixture of fatty acids obtained from lignite wax by oxidation with chromium acid. From this mixture there is cast a film of 20 to 25 μ thickness which in view of its good mechanical properties as to elasticity, extensibility and creasing number is much better adapted for insulating electric conductors than film without the addition of softening agent or with the addition of triphenylphosphate or tricresylphosphate or phthalic acid esters hitherto used.

What we claim is:

1. A process of manufacturing film which comprises dissolving cellulose acetate containing 56 per cent of acetic acid in a mixture of methylene chloride, chloroform and alcohol, adding a mixture of alcohols obtained by oxidizing commercial paraffin and casting the film from this solution.

2. A film which comprises cellulose acetate containing 56 per cent of acetic acid and a mixture of alcohols obtained by oxidizing commercial paraffin.

3. Process of manufacturing film which comprises dissolving in a suitable solvent therefor a compound selected from the group consisting of organic acid esters of cellulose and mixed organic-inorganic acid esters of cellulose, adding

MANUFACTURE OF POLYCHROME PICTURES

Gustav Wilmanns, Wolfen, Kreis Bitterfeld, and Wilhelm Schneider and Ernst Bauer, Dessau, Germany, assignors, by mesne assignments, to Agfa Ansco Corporation, Binghamton, N. Y., a corporation of Delaware

Application April 4, 1936, Serial No. 72,718
In Germany April 10, 1935

10 Claims. (Cl. 95—6)

Our present invention relates to the manufacture of polychrome pictures and more particularly to the manufacture of polychrome pictures from photographic silver halide emulsions.

One of its objects is to provide a process for the production of improved polychrome pictures from silver halide emulsions. Another object are the improved photographic silver halide emulsion layers containing a component which produces color in the developer. Further objects will be seen from the detailed specification following hereafter.

It is known that layers of silver halide emulsion can be developed in color by permitting the products of reaction, produced during the development from developer constituents which have a free amino-group, to condense with reactive phenols or amines to form quinone-imine dyestuffs as for instance indoamines, indoanilines, and indophenols. Dyestuff formation also occurs with bodies which contain a reactive methylene group in which case azomethines are produced. Since, however, in the methods hitherto applied for development in color the component which produces color is incorporated in the developer the method leads merely to monochrome pictures. Attempts to incorporate in the emulsion layer the substance that produces the color have failed, particularly when several layers are used one above the other for producing a polychrome picture. In this case either in applying the second or a later layer to the first layer, or in bringing the material arranged in one or more layers into the developing solution, the components in the emulsion that produce color and are generally soluble in alkali, pass into the adjacent layer into the developer.

The present invention relates to a process in which such diffusion is prevented and the components are fixed in the several colloidal layers. For this purpose there is introduced into the dyestuff component a group which lends the component substantive character with respect to the binding agent of the silver halide emulsion, that is to say, which prevents diffusion in the binding agent of the silver halide emulsion. By introduction of such a group the component can be dissolved in a water-soluble or alkali-soluble form in the colloid without fear that in the finished photographic material the component will diffuse into the adjacent layer or layers. The substantive character produced by introduction of the group can be further strengthened by means of an agent which has a precipitating action on or by means of a group which increases the molecular dimensions of the component. Agents which have a precipitating action are, for instance, diphenylguanidide and diphenylbiguanidide. Groups which increase the molecular dimensions of the component are, for instance, amino groups, benzoyl groups and benzoyl amino groups which are introduced between the component which produces color and the component which imparts substantive character.

Suitable groups for imparting such substantive character and therefore suitable for introduction into the hitherto known color-producers are, for example, diphenyl, dianisidine, tolidine, diphenylcarboxylic acid, diamino-benzoylamino-diphenyl, stilbene, di-aminostilbene, diamino-benzoylaminostilbene, azoxybenzene, hydroxynaphthoic acid-amides, such as 2,3-hydroxynaphthoic acid and 4-(2,3)-hydroxynaphthoylamino-aniline, diaryl-ureas such as diamino-diphenylurea, diamino-benzoylamino-diphenyl-urea, and the urea from amino-benzoylamino-o-sulfanilic acid, benzthiazole, dehydrothiotolidine, aminonaphthols, such as 2-amino-5-naphthole-7-sulfonic acid and 2-aminobenzoylamino-5-naphthole-7-sulfonic acid, terephtaloylbisacetic ester, 2,3-hydroxyanthracene-carboxylic acid, 2,3-hydroxycarbazole-carboxylic acid, aminochrysene, aminopyrene, and aminonaphthylene-oxide, or the like. Components for producing color into which these groups are to be introduced are, for example, phenols such as m-aminophenol, o-o′-dinaphthole, o-hydroxydiphenyl, thymol, 2,5-di (phenylamino)-phenol, aniline, naphthols, such as α-naphthol, α-hydroxynaphthoic acid, chloronaphthole and trichloronaphthole, naphthylamine, for instance, α-naphthylamine, aminonaphthols, for instance, 1,5-aminonaphthole, and all compounds which contain a reactive methylene group, for instance aceto-acetic esters, for instance, bromo-acetoacetic acid ester and acetoacetic anilide, cyano-acetic esters, for instance, cyanacetic acid ester, benzoyl-acetic esters, for instance, benzoylacetic anidide, hydrindenes, for instance, diketohydrinden, pyrazolones, such as phenylmethylpyrazolone and 1-phenyl-3 - phenylpyrazolone, coumaranones, malonic acid anilide, ω-cyanaceto-phenon, hydroxythionaphthene, and the like.

The following example illustrates the invention:

The three-color layers, which may be arranged on one or both sides of the support, contain as components for producing color:

1. Para-(oxynaphthoylamino) - 1 - phenyl - 3 - methyl-5-pyrazolone for red development,
2. Terephthaloylbiacetic acid-anilide for yellow,
3. 3,5-di(phenylamino)-phenol for blue-green.

The alkali salts of these bodies, dissolved in methanol, are stirred into a gelatin solution of 10 per cent strength in the proportion of 1 gram to 50 cc. of the gelatin solution, and the solution is then mixed with 100 cc. of silver halide emulsion. A suitable developer is one consisting of

5 Claims. (Cl. 95—6)

Our present invention relates to color photography and more particularly to a process and material in which color is produced in a colloidal emulsion layer by the action of an oxidation product of a photographic developer on a dyestuff component incorporated in said layer.

This process of color forming development has first been disclosed in U. S. Patents 1,102,028 and 1,055,155 to Fischer.

If a photographic emulsion layer containing these dyestuff components is developed by means of a developer containing free amino groups, for instance phenylene-diamines, especially the mono- or unsymmetrically disubstituted ones like p-dimethylaminoaniline, ethoxy-p-dimethylaminoaniline, there is obtained a colored photographic picture.

The color of the pictures depends upon the dyestuff forming components applied to the layer. Pyrazolones for instance yield blue-red dyes, derivatives of acetoacetic ester yield yellow colorings, and naphthols yield blue colors.

The dyestuff components of Fischer, however, merely lent themselves to the production of pictures in one single color. When dyestuff components which yield various colors by development were incorporated in several superposed layers it became apparent after developing that the components had diffused into all the other layers, viz., that a separation of the color values of the photographed object had not been achieved. Even if components were selected from those listed in the aforementioned patents which are difficultly soluble, i. e., which are capable of being incorporated in the layers in the form of an insoluble precipitate, these components did not show a satisfactory fastness to diffusion, unless they were entirely insoluble, in which case they did not react at all with the developers and merely a black silver picture was produced.

Even for the production of single-colored reversal pictures the dyestuff components were useless inasmuch as they were washed out of the layers during the black-and-white development, so that for the subsequent color development an insufficient amount of them remained in the layers, or at least they were apt to diffuse into the developer itself thereby soiling pictures which were simultaneously developed in another color.

It is therefore an object of the present invention to provide a material in which all these disadvantages and drawbacks are overcome.

A further object is to provide a process by which dyestuff components may be obtained which are soluble in aqueous liquids and which are fast to diffusion once they are incorporated in the photographic emulsion layers.

A further object is to provide dyestuff components which will not be removed from their respective photographic layers by the action of aqueous alkaline liquids such as for instance developing solutions.

A further object of the invention is to provide a color photographic multi-layer material comprising a series of superposed emulsion layers, each layer containing a dyestuff component of the above described kind.

Further objects will be apparent from the detailed specification following hereafter.

This application is to be regarded as a continuation in part of our copending application Ser. No. 72,718 filed April 4, 1936.

The invention is based on the observation that by adding groups to the coupling components having so large a number of atoms that the resultant molecule is substantially increased in size, the dyestuff components, while retaining their solubility in aqueous liquids, do not tend to diffuse from the photographic emulsion layer or into the developing solution.

As dyestuff components which may be substituted by radicals which will increase their molecular size the following may be named by way of example:

All compounds with an active methylene group, for instance acetoacetic ester, bromacetoacetic ester, acetoacetic anilide, cyanoacetic ester, benzoylacetoacetic ester, benzoylacetic acid anilide, terephthaloylacetic ester, hydrindenes such as for instance diketohydrindene, pyrazolones such as for instance 1-phenyl-3-methyl-pyrazolone, 1 - phenyl- 3 -phenyl-pyrazolone, coumaranone, malonic acid anilide-,omega-cyanoacetophenone, hydroxythionaphthene etc. There are further used phenols such as for example meta-aminophenol, o-o′-dinaphthol, o-hydroxydiphenyl,o-o′-dihydroxydiphenyl, substituted naphthols as for instance α-naphthol, dinaphthol, 1,5-hydroxynaphthol, chloronaphthol and trichloronaphthol, substituted aminonaphthols, for instance 1,5-aminonaphthol, phenolcarboxylic acids, for instance salicylic acid, naphthol carboxylic acids, for instance α-hydroxynaphthoic acid. Of the benzene and naphthalene derivatives those hydroxy compounds are especially suitable which in p-position to the hydroxy group have either no substituent at all or a negative substituent such as for instance chlorine, sulfonic acid. Also other substitution products of the above named

GERMAN COLOR FILM

The discovery of the German negative-positive process of color photography has resulted in providing American industry with a process of color reproduction on photographic film which is far superior to any available heretofore as a result of domestic research.

In the well-known technicolor process used in this country, a very complicated process is required. The camera making the picture is quite large and expensive since it contains three reels of black and white film all running simultaneously in order to produce three identical scenes of the original but in different shades of black and white. After filming these three reels, each is then used to make three additional reels in three separate colors. These three color reels are then laid one on top of the other and from that grouping a seventh reel is made which is negative in color. From this negative the eighth reel or positive is made. It is the eighth reel which is shown on the screen. Thus, in the American process eight reels of film are used to produce one reel on the screen. This process was used because of the fact that if the three different color sensitive dies or thin gelatin films were placed on top of one another in order to film a scene directly, the dyes, upon being developed, would blend with one another, the colors thereby intermingling and reducing the definition of the image, thus spoiling the value of the picture. The technicolor process avoided the difficulty by making the individual color films separately.

The Germans, however, found a means for preventing blending of the different color layers, thereby enabling them to film the scene directly on one color negative. From this negative, one or more positives are made. Therefore, in the American process, eight reels of film are used to produce one reel for the screen, whereas the AGFA process requires only two reels.

The extent to which American industry realizes the economic possibilities inherent in the application of this simplified method of producing true color reproduction on photographic film is indicated by the fact that thus far seven film manufacturers have seen fit to expend the effort and money necessary to send qualified scientists to Germany to obtain information in this field of activity.

Report No. PB-25659 published by the Office of Technical Services of the Department of Commerce contains detailed information essential for the application of this process.

See attached letters.

Figure 3.144: Advanced technology to produce and process color film was developed in the German-speaking world and transferred to other countries after World War II [NARA RG 40, Entry UD-75, Box 58, Folder TIID Discards].

3.8 Materials Science

Materials science covers the creation of solid chemical compounds that make useful materials for various applications and products. For simplicity, this field can be divided into several areas, and German-speaking scientists played major roles in all of them:

3.8.1. Polymers

3.8.2. Ceramics and crystallography

3.8.3. Glass

3.8.4. Metals

3.8.1 Polymers

Creators from the German-speaking world led most of the development of polymers, including plastics and synthetic rubbers, which are now ubiquitous in consumer products.[15]

As shown in Fig. 3.145, polystyrene was first created in 1839 by Johann Eduard Simon (German states, 1789–1856), and developed further in 1845 by August Wilhelm von Hofmann (1818–1892) and John Blyth (Scottish but studied in Germany, 1814–1871). In 1929, Hermann Mark (Austrian, 1895–1992) and Carl Wulff (German?, 18??–19??) greatly improved the process of producing polystyrene. In the 1940s, Fritz Stastny (Austrian, 1908–1985) created expanded or porous polystyrene (Styrofoam). Polystyrene is used to make a wide variety of consumer products, and Styrofoam is used to make thermally insulated containers and protective packaging (Fig. 3.146).

Cellulose acetate was first created in 1865 by Paul Schützenberger (Franco-German, 1829–1897), and produced in larger quantities in 1903 by Arthur Eichengrün (German, 1867–1949) and Theodore Becker (German?, 18??–19??). The brothers Camille Dreyfus (Swiss, 1878–1956) and Henri Dreyfus (Swiss, 1882–1944) developed cellulose acetate yarn in 1913. Cellulose acetate has been used for photographic film, eyeglass frames, yarn, clothing, and other products, as illustrated in Fig. 3.147.

Eugen Baumann (German, 1846–1896) discovered photopolymerization and created polyvinyl chloride in 1872 (Fig. 3.148). Friedrich (Fritz) Klatte (German, 1880–1934) developed an improved method of producing polyvinyl chloride in 1913. Polyvinyl chloride is widely used for making water drain pipes and pipe fittings.

Phenol formaldehyde (phenolic) resin was first created in 1891 by Adolf von Baeyer (German, 1835–1917) and Werner Kleeberg (German, 18??–19??), and developed further in 1902 by Adolf Luft (German?, 18??–19??). Adolf von Baeyer won the Nobel Prize in Chemistry in 1905 (p. 459). In 1907, Leo Baekeland (Belgian but studied under August Kekulé, 1863–1944) began producing and commercializing phenolic resin under the trade name of Bakelite; phenolic resin was also sold under other trade names. Phenolic resin was used to make early plastic products such as telephone cases. See Fig. 3.149.

Figure 3.149: Phenol formaldehyde (phenolic) resin was first created in 1891 by Adolf von Baeyer and Werner Kleeberg, and developed further by Adolf Luft and Leo Baekeland. Phenolic resin was commercialized as Bakelite and other trade names and used to make early plastic products such as telephone cases.

In 1897, Wilhelm Krische (German, 1859–19??) and Friedrich Adolph Spitteler (German, 1846–1940) created a natural plastic (later dubbed Galalith) by purifying and crosslinking casein milk protein, as shown in Fig. 3.150. Galalith was also used to make a number of early plastic products.

Polyethylene was first created in 1898 by Hans von Pechmann (German, 1850–1902). In 1900, Eugen Bamberger (German, 1857–1932) and Friedrich Tschirner (German?, 18??–19??) determined the chemical structure of polyethylene. Karl Ziegler (German, 1898–1973) developed an improved method of producing polyethylene in 1952, and won the Nobel Prize in Chemistry in 1963 (p. 498). Polyethylene has been widely used to make plastic bags (Fig. 3.151), due to its flexibility and the low cost of Ziegler's production process.

Polycarbonate was first created in 1898 by Alfred Einhorn (German, 1856–1917). In 1953, Hermann Schnell (German, 1916–1999) developed an improved method of producing polycarbonate. Because polycarbonate is very rugged, it is used to make products such as compact discs, water bottles, cell phone cases, and safety glasses. See Fig. 3.152.

Friedrich (Fritz) Klatte (German, 1880–1934), shown in Fig. 3.153, created polyvinyl acetate in 1912. It has been used worldwide as white glue ever since.

Otto Röhm (German, 1876–1939) and Walter Hermann Bauer (German, 1893–1968) created polymethylacrylic (plexiglass) in 1928. Plexiglass pieces from a circa 1942 German aircraft windshield are shown in Fig. 3.154.

Some German-speaking scientists who made important contributions to rubber included (Fig. 3.155):

- Carl Harries (German, 1866–1923) studied the polymer structure of rubber.
- Fritz Hofmann (German, 1866–1956) produced synthetic rubbers.
- Kurt Gottlob (Austrian, 1881–1925) developed emulsion polymerization and improved vulcanization.
- Kurt Meyer (German, 1883–1952) studied the structure of cellulose and the effect of entropy on rubber elasticity.
- Herman(n) Mark (Austrian, 1895–1992) studied the structure of cellulose.
- Eugen(e) Guth (Hungarian, 1905–1990) developed a mathematical model using entropy to calculate the elasticity of rubber.

As shown in Fig. 3.156, Eduard Tschunkur (German, 1874–1946) and Walter Bock (German, 1895–1948) created styrene-butadiene synthetic rubber (Buna S) in 1929. It is now used to make most tires.

Similarly, Eduard Tschunkur, Helmut Kleiner (German, 1902–1987), and Erich Konrad (German, 1894–1975) created acrylonitrile butadiene synthetic rubber (Buna N) in 1930. It is now used for products such as latex-free nitrile rubber gloves (Fig. 3.157).

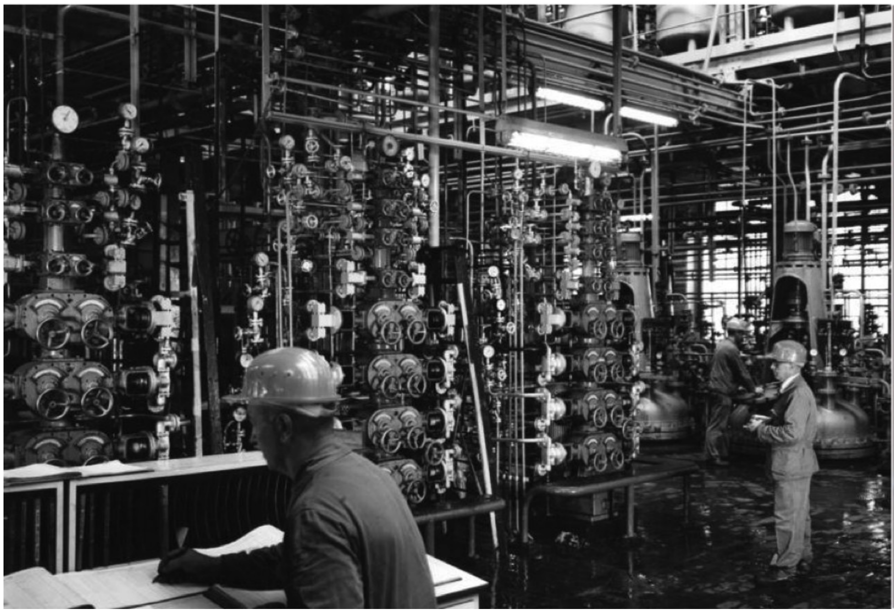

Figure 3.157: Eduard Tschunkur, Helmut Kleiner, and Erich Konrad created acrylonitrile butadiene synthetic rubber (Buna N) in 1930; it is now used for products such as latex-free nitrile rubber gloves.

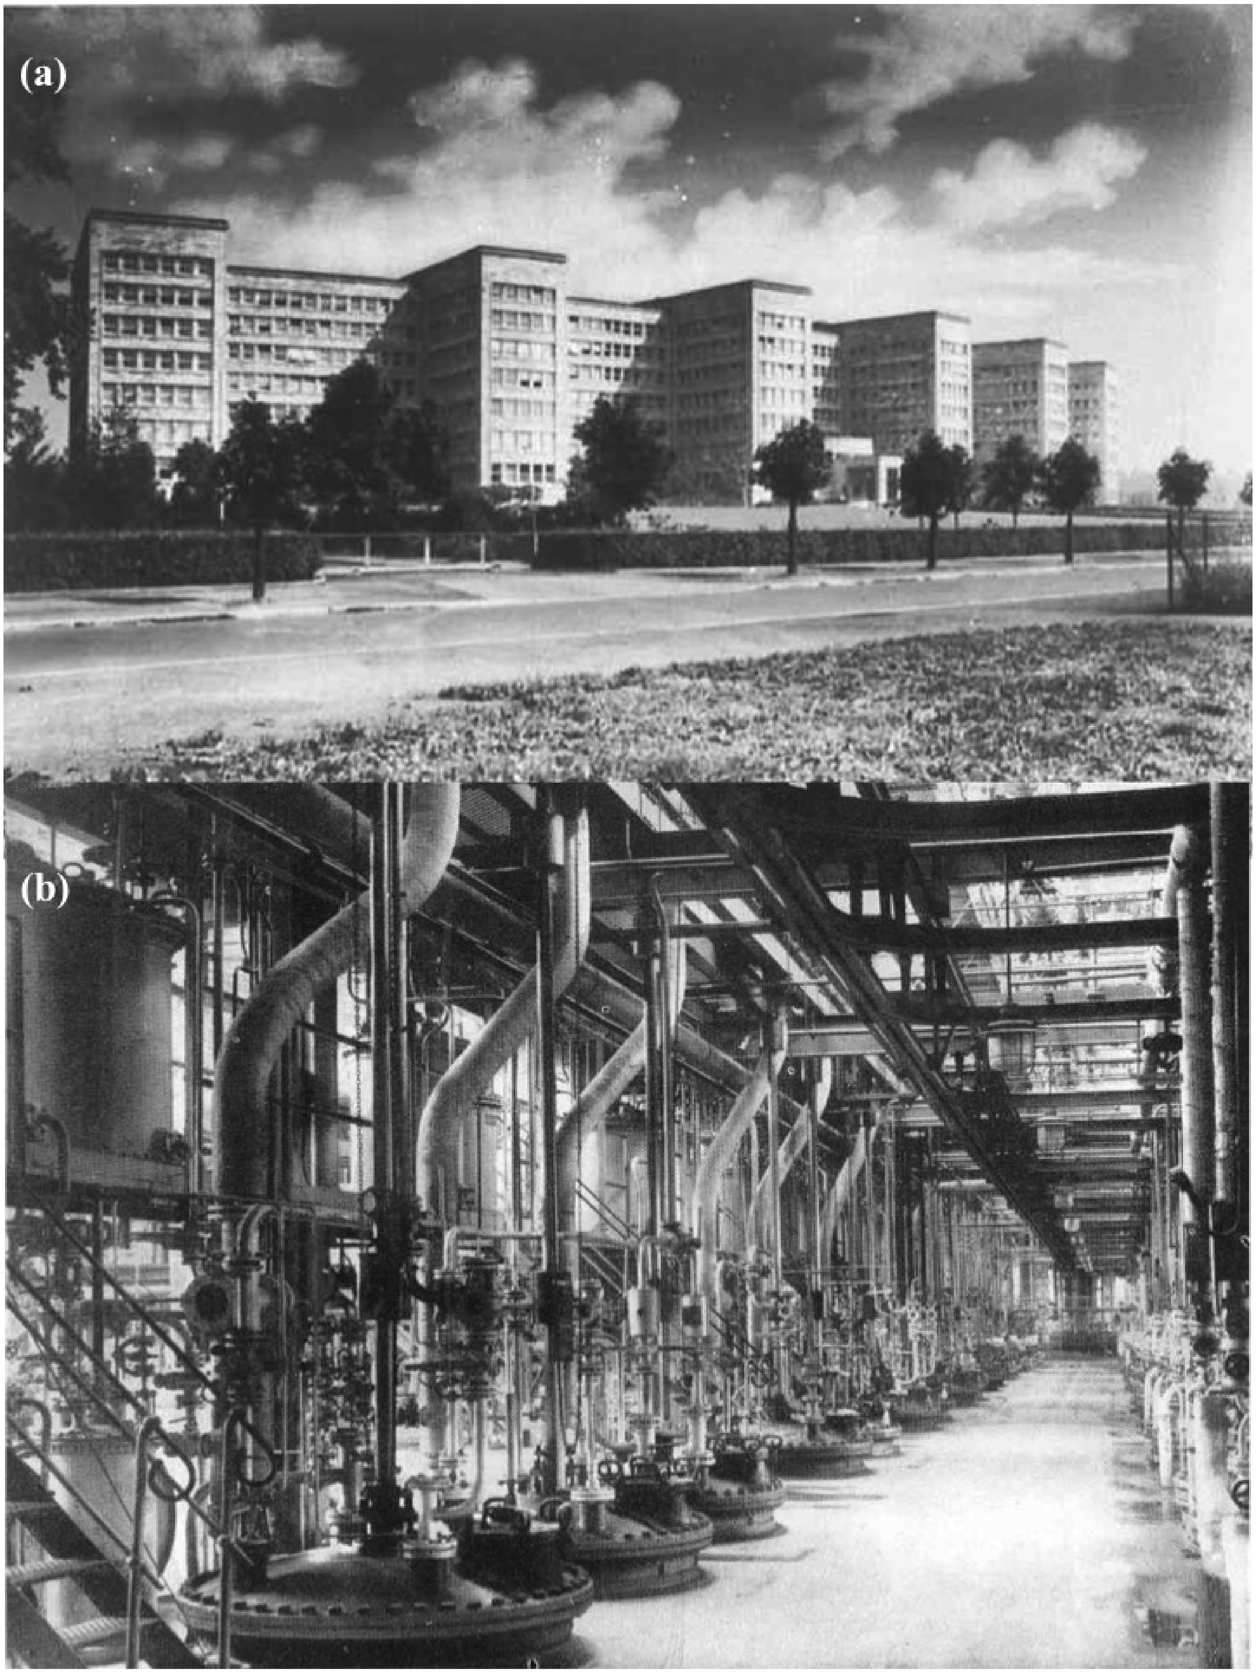

Figure 3.158: I.G. Farben headquarters in Frankfurt am Main (1930–1945) and production of butadiene or buna synthetic rubber.

Polyacrylonitrile (Orlon) was first created in 1930 by Hans Fikentscher (German, 1896–1983) and Claus Heuck (German?, 18??–19??). Beginning in 1938, it was produced in the form of fibers by Herbert Rein (German, 1899–1955). See Fig. 3.159.

As illustrated in Fig. 3.160, Otto Bayer (German, 1902–1982) created polyurethane in 1937. Polyurethane is now used for sprayable thermal insulation, surface coatings [BIOS 629], memory foam, Spandex, and other products.

Paul Schlack (German, 1897–1987) created polyamide (better known as Nylon or Perlon) in the 1930s. Wallace Carothers (American, 1896–1937) independently produced Nylon around the same time in the United States but became much better known than Schlack. Nylon/Perlon is widely used now to make thread, rope, and solid objects (Fig. 3.161).

Karl Rehn (German, 19??–19??) and Karl Ziegler (German, 1898–1973), shown in Fig. 3.162, produced polypropylene in 1951. Ziegler won the Nobel Prize in Chemistry in 1963 (p. 498). Polypropylene is widely used for products that must not crack even after repeated bending and stress, such as plastic hinges and centrifuge tubes.

Some other creators who made important contributions to polymers included (Fig. 3.163):

- Wilhelm Rudolph Fittig (German, 1835–1910) studied the chemistry of polymers.
- Bernhard Tollens (German, 1841–1918) developed urea-formaldehyde resin polymers.
- Oscar Troplowitz (German, 1863–1918) created adhesive bandages and adhesive tape in 1901.
- Hermann Staudinger (German, 1881–1965) studied polymer structures. He won the Nobel Prize in Chemistry in 1953 (p. 474).
- Werner Kuhn (Swiss, 1899–1963) was especially noted for his work on the physical chemistry of polymers. He applied the laws of statistical physics to polymer molecules to explain the temperature dependence of viscosity and elasticity in rubber and other polymers.
- Victor Garten (German, 19??–19??) conducted advanced research on polymers in Germany during World War II, then moved to Australia after the war to continue his research. In Australia, he produced revolutionary electrically conducting polymers that were quite likely based on wartime German work. The 2000 Nobel Prize in Chemistry was awarded to Alan Heeger, Alan MacDiarmid, and Hedeki Shiakawa for rediscovering electrically conducting polymers much later.

Polymer production also makes extensive use of the Diels-Alder reaction, which was developed by Otto Diels (German, 1876–1954) and Kurt Alder (German, 1902–1958). They both won the Nobel Prize in Chemistry in 1950 for that discovery. See pp. 468 and 483.

As shown in Fig. 3.164, George de Mestral (Swiss, 1907–1990) invented Velcro hook-and-loop fasteners in 1941. They were subsequently used in everything from the space program to sportswear.

After World War II, vast amounts of information on polymers were transferred from the German-speaking world to Allied countries: large numbers of scientists, reports on interrogations of scientists, patents, BIOS/CIOS/FIAT reports, samples, hardware, and even complete factories. See for example Fig. 3.165. Thus it was the innovations of German-speaking creators that dominated the field of polymers from the first inventions of polymers in the nineteenth century to the boom in commercial polymer production and applications in the latter half of the twentieth century.

Hans Fikentscher (1896–1983) created polyacrylonitrile (1930)

Claus Heuck (18??–19??) created polyacrylonitrile (1930)

Herbert Rein (1899–1955) produced polyacrylonitrile fibers (1938)

Mr. Howland H. Sargeant
Department Director J.I.O.A.
Department of Commerce
Washington, D.C.

Dear Mr. Sargeant:

This will acknowledge with thanks copies of Synthetic Fibers Team reports which you have sent me.

You are interested in determining the economic aspects of our reports - i.e., assistance to industry, reduction in costs, creation of jobs, and improvement of products, etc.

From the pure research standpoint, I think that a considerable number of man years have been saved in synthetic fiber research. The Germans do their research work thoroughly and we will not have to repeat what they have done - merely pick up the research and go forward. This represents a considerable saving.

We found developments in chemical engineering, especially concerned with the development of continuous processes, which may have a significant bearing upon reduction in costs. We believe that American engineers will be able to improve these processes. The important thing is that we have obtained the basic ideas for further development in engineering from this Technical Mission.

With respect to creation of jobs, this Mission has been of assistance from the standpoint of helping us to resolve more rapidly the technical worth of our new research products which are in the "test tube" or semi-works stage. That is, we have been able to compare our research products with the German products and developments and discuss with their chemists the intrinsic worth of their products, securing their opinions regarding the needs of industry. Parrying their thinking with ours has allowed a quicker resolution of the worth of our products and thus a crystallization of our decision to go ahead with the creation of new industries.

Sincerely yours,

DEVELOPMENT SECTION

Figure 3.165: The Assistant Director of the Development Section at the U.S. Du Pont company wrote that because of all of the information on polymers that his company acquired from Germany and Austria after the war, "a considerable number of man years have been saved in synthetic fiber research" at his company [NARA RG 40, Entry UD-75, Box 61, Folder Booster Letters].

3.8.2 Ceramics and Crystallography

Large numbers of German-speaking scientists played major roles in ceramics and crystallography. [16] Some examples are shown in Figs. 3.166–3.171 and briefly discussed below.

In the 1930s and 1940s, Eberhard Both (German, 1910–19??) conducted and led research at Vacuum Schmelze AG in Hanau on the development of new ceramic materials and metal alloys with improved high-temperature and/or magnetic properties. After the war, he moved to the U.S. Army's laboratory in Fort Monmouth, New Jersey, where he initiated and ran similar research programs. ?? Kolmar (German, 19??–19??) was also involved in the Vacuum Schmelze work at Hanau and may have moved to the United States after the war.

At Siemens at Neuhaus near Sonnenberg during World War II, Wilhelm Buessem (German, 1903–1992), ?? Koenig (German, 19??–19??), Hans Joachim Reusch (German, 19??–19??), and Berthold Weber (German, 19??–19??) developed alumina-based ceramics for electronic components and for turbojet engine blades. They also created new titanium-oxide-based dielectrics for capacitors. After the war, Buessem moved to the U.S. Army's Fort Monmouth laboratory, and Weber went to the Air Force's laboratory at Wright Field, Ohio.

Adolf Hugo Dietzel (German, 1902–1993) studied silicates and other ceramic materials at the Kaiser Wilhelm (later Max Planck) Institute for Silicate Research during the period 1930–1969.

Wilhelm Eitel (German, 1891–1979) was director of the Kaiser Wilhelm Institute for Silicate Research 1926–1945, and continued his work on silicates and other materials in the United States after the war.

Johann Hessel (German, 1796–1872) was one of the pioneers of classifying crystal shapes and describing them mathematically. He also studied the composition of feldspar and other minerals.

At Degussa's research facility at Stierstadt during World War II, Gustav Jaeger (German, 19??–19??) and Eugen Ryschkewitz (German, 19??–19??) developed ceramic materials based on alumina, other metal oxides, and silicon carbide for a variety of applications, including electronic components, turbojet engine blades, cutting tools. After the war, Ryschkewitz moved to Wright Field, Ohio to continue this work.

At the wartime Hescho facility at Hermsdorf near Jena, ?? Kaase (German, 19??–19??), Fritz Obenaus (German, 1904–1980), ?? Rath (German, 19??–19??), and ?? Scheid (German, 19??–19??) developed high-temperature ceramics for turbojet engine blades. They created and tested several different ceramic materials, including soapstone-based Calit, silicon-carbide-based Sicalit, and kaolin-based Ardostan. They also developed titanium-oxide-based dielectrics for capacitors.

Ralph Kronig (German, 1904–1995) developed detailed theoretical models of the behavior of X-rays and electrons in crystal lattices, thus helping to better understand the structures and properties of crystalline materials, including ceramics, metals, and semiconductors.

Max von Laue (German, 1879–1960) pioneered the use of X-rays to analyze the atomic arrangements in crystals and ceramic materials. He focused primarily on theoretical methods of analyzing the results, and the experiments were implemented by Walter Friedrich (German, 1883–1968) and Paul Knipping (German, 1883–1935). Max von Laue won the Nobel Prize in Physics in 1914 for this work. Professor G. Granqvist, Chairman of the Nobel Committee for Physics, explained the importance of the methods and discoveries of von Laue's group [https://www.nobelprize.org/prizes/physics/1914/press-release/]:

> This was the situation when von Laue placed a research medium of the highest import at the disposal of science by virtue of his epoch-making discovery of the interference of X-rays and, at the same time, proved that X-rays, as is the case with light rays, consist of progressive transversal waves.
>
> Previous research had indicated, as is mentioned in the foregoing, that it was highly probable that, if X-rays are wave motions of the same type as light rays, then their wavelengths would have to be of an order of 10^{-9} cm. In order to obtain clear interference phenomena of the same type as those which are caused when light rays pass a grating it was necessary for the distance between the grating slits to be of an order of 10^{-8} cm. But this is approximately the distance between the molecules of a solid body and it was in this manner that von Laue arrived at the idea of employing, as a diffraction grating, a solid body with regularly-arranged molecules, e.g. a crystal. As early as 1850 Bravais had introduced into crystallography the assumption that the atoms composing the various crystals are arranged in regular groups, so-called three-dimensional lattices or space-lattices, whose constants could be calculated with the aid of crystallographic data.
>
> However, the theoretical basis of a space-lattice was unknown and thus it was first necessary for von Laue to develop this theory if else the investigation were to have a value. This he did mainly according to the same approximations as those conventional to the science of optics as applied to normal one-dimensional lattices.
>
> Von Laue left the execution of the experimental work in the hands of W. Friedrich and P. Knipping. The apparatus which they employed consisted of a lead box into which they admitted a thin bundle of X-rays which they directed so as to fall upon a precisely oriented crystal. Sensitized film was positioned both behind and at the sides of the crystal. Already the preparatory tests showed that the intensity maxima which had been anticipated by von Laue became evident in the form of blackened spots on the film positioned behind the crystal. [...]
>
> As a result of von Laue's discovery of the diffraction of X-rays in crystals proof was thus established that these light waves are of very small wavelengths. However, this discovery also resulted in the most important discoveries in the field of crystallography. It is now possible to determine the position of atoms in crystals and much important knowledge has been gained in this connection. We can anticipate further discoveries of equal note

> in the future. It is thus rendered likely that experimental research into the influence of temperature upon diffraction will provide the solution to the question of a zero-point energy, or will at least be of some assistance in arriving at a solution to this problem, as the temperature factor assumes a different value according to whether a zero-point energy exists or not. However, the direct results of this discovery of diffraction are of no less importance: it is now possible to subject the X-ray spectra to direct examination, their line spectra can even be photographed, and science has thus been enriched by a method of research whose full implications can not yet be fully appreciated.

At Lutz & Co. at Lauf an der Pegnitz during World War II, Nikolaus Lutz (German, 19??–19??) and Franz Rother (German, 19??–19??) developed new ceramic materials for specialized electronic applications. Their ceramics included titanium-oxide-based dielectrics, iron-oxide-based magnetic ceramics, magnesium oxide-based ceramics, and other materials with semiconducting and/or magnetic properties.

Herman(n) Mark (Austrian, 1895–1992) primarily focused on polymer research, yet he carried out some important work with X-ray crystallography as well.

Friedrich Mayer (German, 19??–19??) developed metal-oxide coatings and other ceramic coatings to harden metal tool surfaces.

Eilhard Mitscherlich (German states, 1794–1863) made several important contributions to crystallography. He is especially remembered for his discovery of crystallographic isomorphism, or the ability of the same chemical composition to form crystals of somewhat different shapes depending on the alignment of the component atoms.

Friedrich Mohs (German states, 1773–1839) studied many aspects of crystallography. He is particularly famous for introducing his mineral hardness scale in 1812. The Mohs scale ranks minerals from softer (starting with 1 for talc) to harder (ending with 10 for diamond) based on which mineral receives scratches when two dissimilar minerals are rubbed together. It is still widely used today.

Paul Niggli (Swiss, 1888–1953) was another important pioneer of X-ray crystallography, and further developed the mathematical methods of describing crystal structures.

Hans Pulfrich (German, 19??–19??) developed ceramics for electrical applications at AEG and Telefunken from the 1920s to the 1960s.

Working at the Aerodynamische Versuchsanstalt (AVA) at Göttingen during World War II, L. Ritz (German, 19??–19??) designed and demonstrated high-temperature ceramic heat exchangers for turbojet engines and other applications.

At the Luftfahrtforschungsanstalt (LFA) in Brunswick during World War II, Ernst Schmidt (German, 19??–19??) and H. Söhngren (German, 19??–19??) developed high-temperature ceramics for turbojet engine blades.

Arthur Schoenflies (German, 1853–1928) applied advanced mathematical methods such as group theory to the analysis of crystal structures. “Schoenflies notation” is still widely utilized in crystallography and solid state physics.

Working at various German companies from the 1930s to the 1950s, Carl Schusterius (German, 19??–19??) developed and patented novel ceramics for a wide variety of electrical components, as well as for other applications such as dental prostheses.

At the Machinenfabrik Augsburg-Nürnberg A.G., D. Emil Sorensen (German, 19??–19??) developed high-temperature ceramics for turbojet engine blades during World War II.

Gustav Tschermak von Seysenegg (Austrian, 1836–1927) studied the crystallographic structures and chemical compositions of a wide variety of minerals and even meteorites.

Christian Samuel Weiss (German states, 1780–1856) was one of the pioneers of classifying crystal shapes and describing them mathematically.

F. Werther (German, 19??–19??) developed titanium-oxide-based ceramics for various applications.

For German-speaking creators and creations in the closely related fields of solid state physics, semiconductor devices, superconductivity, and piezoelectricity, see Section 6.5.

Large amounts of information, materials, and scientists involved in work on advanced ceramics were transferred to other countries after World War II (Fig. 3.172). See for example:

While the postwar technology transfer involved a broad range of advanced ceramic materials, one especially important area was synthetic mica for electronics applications. Due to a shortage of real mica in wartime Germany, scientists invented synthetic mica-like ceramics that proved to be superior to the original material. After the war, large amounts of information, materials, and scientists involved in work on synthetic mica were transferred to other countries, as documented in reports such as:

3.8.3 Glass

Glass production has a history going back to ancient times, and has been practiced worldwide. The glassmaking industry was especially prominent and advanced in the German-speaking world, dating back many centuries in Thuringia, Bohemia, and other regions. As scientific research gained greater prominence in the German-speaking world around 1800, it was combined with the older traditions of glassmaking craftsmanship, resulting in a number of major technological advances in methods of producing and utilizing glass.

Joseph von Fraunhofer (German states, 1787–1826) made a number of early improvements in glass manufacturing processes for optics and other applications. He then used his glass elements to create new optical instruments such as spectroscopes (pp. 961 and 1260).

Other especially important early glassmakers who produced and used improved optical elements and optical instruments included:

- Simon Plössl (Austrian, 1794–1868, Fig. 6.228), who was particularly noted for producing achromatic (non-color-distorting) lenses for microscopes and telescopes.
- Georg Johann Oberhäuser (German states, 1798–1868) and Edmund Hartnack (German, 1826–1891), who also produced early microscopes. Hartnack invented liquid-immersion lenses to achieve higher resolution. See p. 1269.
- Carl Zeiss (German, 1816–1888) and Ernst Abbe (German, 1840–1905), who revolutionized the production of high-quality microscopes at the Zeiss optical company (p. 1270).
- Carl Kellner (German states, 1826–1855) and Ernst Leitz I (German, 1843–1920) at the Leitz optical company (p. 1275), another producer of high-quality microscopes and other optical instruments.

Arguably the most important glass scientist in the German optical industry, though, was Otto Schott (German, 1851–1935), who is shown in Fig. 3.173. In partnership with the Zeiss company, he founded the Schott glassworks in Jena and created a variety of special-purpose types of glass, including optical glass (1873, for Zeiss microscopes to achieve the maximum diffraction-limited resolution), lithium glass (1879), and borosilicate glass (1887). Borosilicate glass is resistant to thermal stress (when exposed to temperature changes, it expands and contracts less than normal glass, and therefore is much less likely to shatter when heated or cooled), so it is still widely used to make glassware containers for cooking and laboratory work.

One area of traditional German glassmaking craftsmanship, dating back before 1800, was producing long, flexible fibers of glass. The glass fibers were used for decoration and other applications.

Apparently drawing upon those German glass fiber methods, Hermann Hammesfahr (German, 1845–1914) moved to the United States and began producing and patenting fiberglass threads, cloth, and insulation. See Fig. 3.174. After a slow start, his work eventually prompted broader American industrial interest in fiberglass in the twentieth century.

Even as Hammesfahr took fiberglass technology to the United States, fiberglass production and applications continued to advance in the German-speaking world. For example, Ulrich Hütter (Austrian, 1910–1990, Fig. 3.175) produced glass-fiber-reinforced polymers in Germany during and after World War II for applications ranging from aircraft structures to wind turbine blades.

Similarly, Alfred Schmid (Swiss, 1899–1968) demonstrated how to make very strong yet very light composite materials by reinforcing processed wood and/or polymers with fiberglass. After the war, Schmid transferred that technology to Allied countries (Fig. 3.175). For example, BIOS 563, *The German Radio Component Industry*, p. 18, reported:

> A synthetic material composed of fibreglass coated with an artificial resin had been developed, and was used to coat articles made of a low-density homogeneous wood with a coating 0.02 mm thick. This resulted in an article of light weight but having great strength. It was claimed that both tensioned and compressional forces could be dealt with. Dr. Schmid envisaged the aircraft of the future as being made from glass coated homogeneous wood for light weight combined with great strength. He also claimed that repairs to the skin, if damaged, could be done simply by the application of more of the fibre-glass material.

As shown in Fig. 3.176, an 11 May 1945 document from the U.S. Army Air Forces stated [AFHRA A5729 electronic pp. 1650–1651]:

> Glass types which are not available in this country and which might be of considerable value to American manufacturers are known to have existed in Germany before the war and it is recommended that a survey be made[...]

Indeed, numerous BIOS, CIOS, and FIAT reports documented widespread production and use of advanced glass and fiberglass products in the German-speaking world, as well as the transfer of those technologies to Allied countries after World War II (Fig. 3.177). See for example:

During World War II, the Zeiss infrared Lichtsprechgerät was used for optical transmission of voice communications over distances up to several kilometers (pp. 1131, 1142). That device also would have been quite suitable for use with optical fibers instead of free-space transmission. Fiber optics would have given the signals far more privacy, which would have been an obvious advantage during wartime. More historical research is needed to determine if optical fibers (made of either glass or polymers) were indeed used in conjunction with optical data transmissions in wartime Germany.

In fact, further archival research on all aspects of the history, accomplishments, and global influence of the German-speaking world on glassmaking technologies and applications could be quite enlightening.

Otto Schott (1851–1935) created optical glass (1873), lithium glass (1879), borosilicate glass (1887)

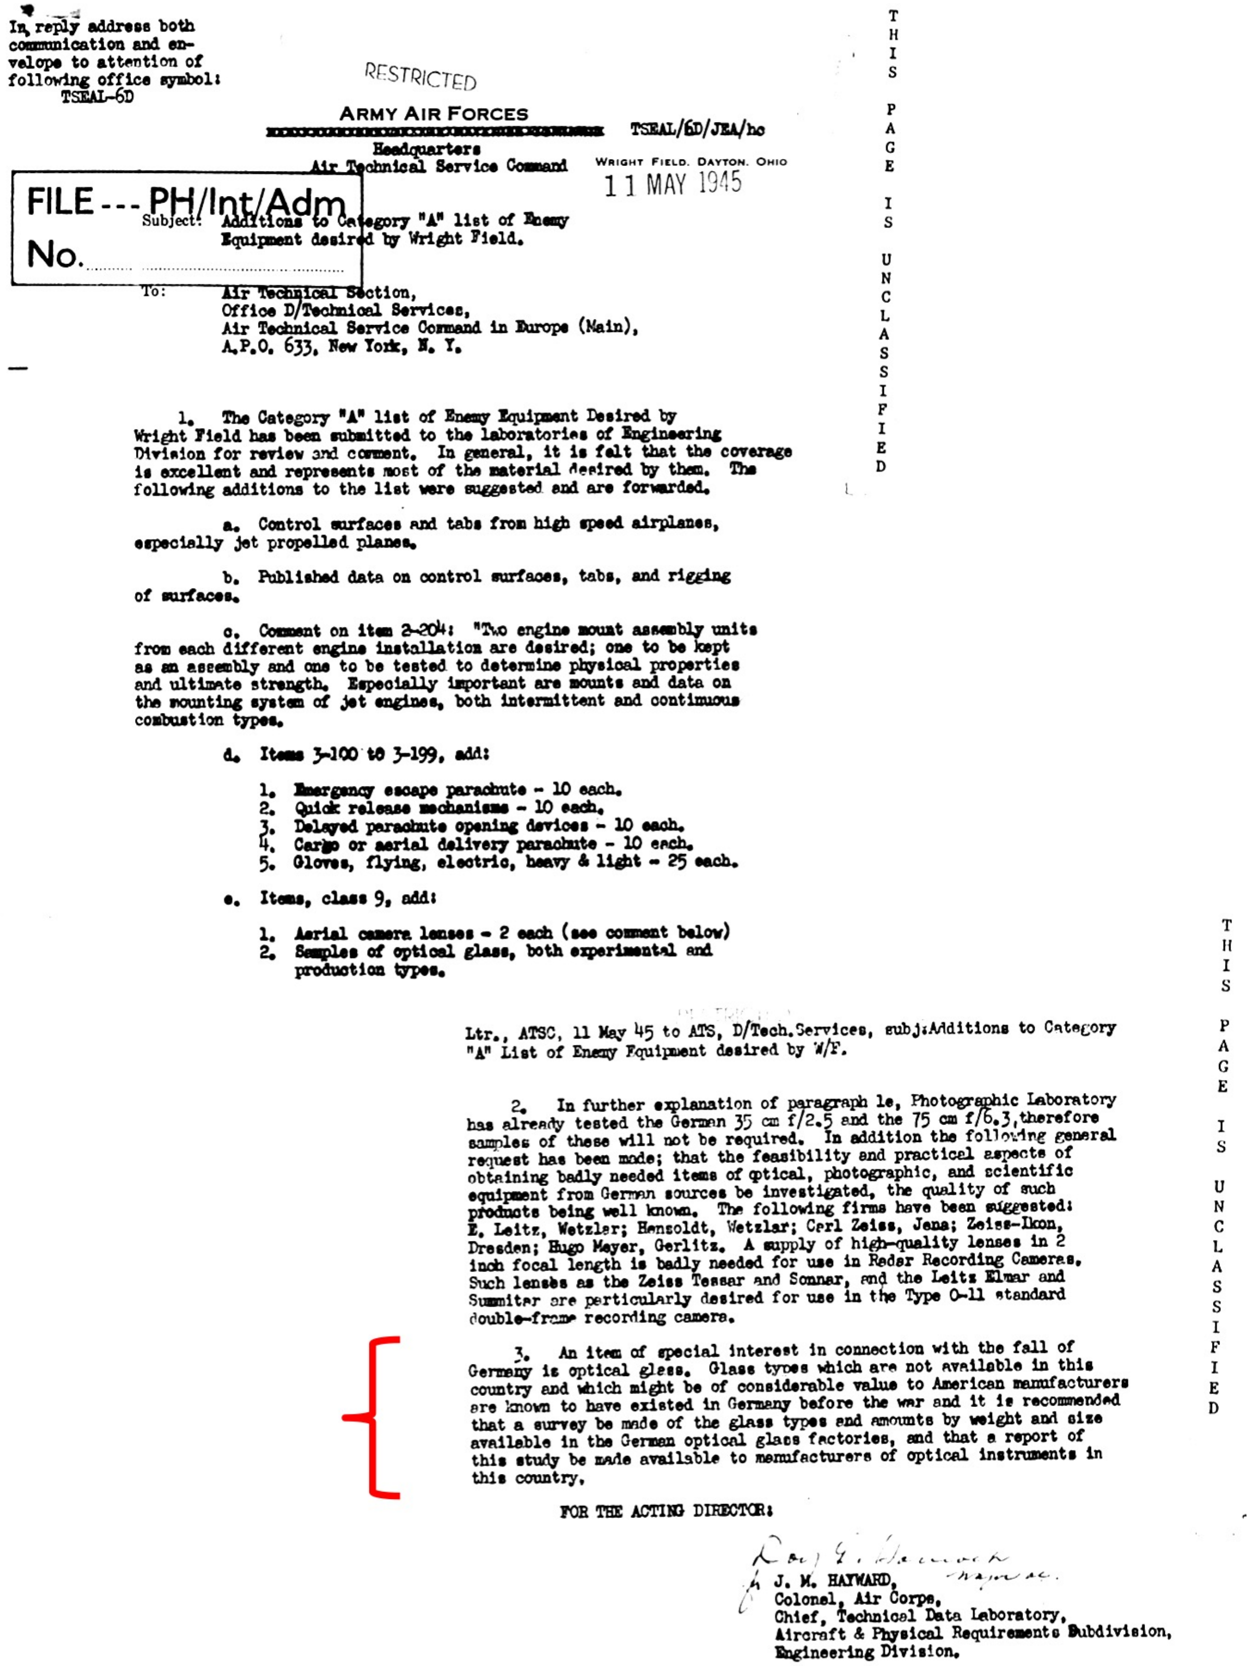
2.3. Fibre glass Developments

A synthetic material composed of fibreglass coated with an artificial resin had been developed, and was used to coat articles made of a low-density homogeneous wood with a coating .02 mm thick. This resulted in an article of light weight but having great strength. It was claimed that both tensioned and compressional forces could be dealt with. Dr.Schmid envisaged the aircraft of the future as being made from glass coated homogeneous wood for light weight combined with great strength. He also claimed that repairs to the skin, if damaged, could be done simply by the application of more of the fibreglass-resin material.

Figure 3.175: Ulrich Hütter and Alfred Schmid separately demonstrated fiberglass-reinforced polymers and fiberglass-reinforced processed wood composite materials during World War II, then transferred that technology to Allied countries after the war [BIOS 563].



In reply address both communication and envelope to attention of following office symbol:

FILE --- PH/Int/Adm
No.

Subject: Additions to Category "A" list of Enemy Equipment desired by Wright Field.

To: Air Technical Section,
Office D/Technical Services,
Air Technical Service Command in Europe (Main),
A.P.O. 633, New York, N. Y.

1. The Category "A" list of Enemy Equipment Desired by Wright Field has been submitted to the laboratories of Engineering Division for review and comment. In general, it is felt that the coverage is excellent and represents most of the material desired by them. The following additions to the list were suggested and are forwarded.

a. Control surfaces and tabs from high speed airplanes, especially jet propelled planes.

b. Published data on control surfaces, tabs, and rigging of surfaces.

c. Comment on item 2-204: "Two engine mount assembly units from each different engine installation are desired; one to be kept as an assembly and one to be tested to determine physical properties and ultimate strength. Especially important are mounts and data on the mounting system of jet engines, both intermittent and continuous combustion types.

d. Items 3-100 to 3-199, add:

1. Emergency escape parachute - 10 each.
2. Quick release mechanisms - 10 each.
3. Delayed parachute opening devices - 10 each.
4. Cargo or aerial delivery parachute - 10 each.
5. Gloves, flying, electric, heavy & light - 25 each.

e. Items, class 9, add:

1. Aerial camera lenses - 2 each (see comment below)
2. Samples of optical glass, both experimental and production types.

THIS PAGE IS UNCLASSIFIED

Ltr., ATSC, 11 May 45 to ATS, D/Tech.Services, subj:Additions to Category "A" List of Enemy Equipment desired by W/F.

2. In further explanation of paragraph 1e, Photographic Laboratory has already tested the German 35 cm f/2.5 and the 75 cm f/6.3, therefore samples of these will not be required. In addition the following general request has been made; that the feasibility and practical aspects of obtaining badly needed items of optical, photographic, and scientific equipment from German sources be investigated, the quality of such products being well known. The following firms have been suggested: E. Leitz, Wetzlar; Hensoldt, Wetzlar; Carl Zeiss, Jena; Zeiss-Ikon, Dresden; Hugo Meyer, Gerlitz. A supply of high-quality lenses in 2 inch focal length is badly needed for use in Radar Recording Cameras. Such lenses as the Zeiss Tessar and Sonnar, and the Leitz Elmar and Summitar are particularly desired for use in the Type O-11 standard double-frame recording camera.

3. An item of special interest in connection with the fall of Germany is optical glass. Glass types which are not available in this country and which might be of considerable value to American manufacturers are known to have existed in Germany before the war and it is recommended that a survey be made of the glass types and amounts by weight and size available in the German optical glass factories, and that a report of this study be made available to manufacturers of optical instruments in this country.

FOR THE ACTING DIRECTOR:

J. M. HAYWARD,
Colonel, Air Corps,
Chief, Technical Data Laboratory,
Aircraft & Physical Requirements Subdivision,
Engineering Division.

Figure 3.177: Numerous BIOS, CIOS, and FIAT reports documented widespread production and use of advanced glass and fiberglass products in the German-speaking world, as well as the transfer of those technologies to Allied countries after World War II [BIOS 1340].

3.8.4 Metals

A common view is that by 1945, metallurgy was less advanced in the German-speaking world than elsewhere, due to the scarcity of some types of metal ores in German-speaking areas and the international blockade of metal imports during the wars. In fact, a huge number of German-speaking scientists made major contributions to metallurgy from the nineteenth century through WWII, and then many of these creators and their creations were transferred to the United States and other countries [Maier 2007]. Just a few illustrative examples are shown in Figs. 3.178–3.186 and discussed below in alphabetical order.

Heinrich Adenstedt (German, 1910–1991) was an expert on titanium and other metal alloys who came to the United States after the war [Figs. 3.178–3.179]. Both in Germany during the war and in the United States after the war, he worked very closely with jet/helicopter/tank engine designer Anselm Franz (pp. 1381 and 1739–1740). In a 1948 article [Adenstedt 1948], Adenstedt listed several advanced iron-based (steel) alloys that were developed and used in Germany before and during WWII, including Tinidur (Titanium Nickel Durable alloy), Cromadur (Chromium Manganese Durable alloy), FKDM 10 (V, Cr, W, Mo), FKM 10 (V, Cr, Mo), and MC 120 (Mo, Cr). Some of the related alloys that were also developed and used then included Vanidur (Vanadium Nickel Durable alloy) and Sinidur (Silver Nickel Durable alloy). Most of those advanced alloys were produced by Krupp and were intended for jet engine components, due to their heat resistance and good structural properties. They are still used for that purpose even today.

Georgius Agricola, or Georg Bauer (German states, 1494–1555, Fig. 3.10), discovered bismuth around 1540 and conducted extensive work on metallurgy.

Kurt Anderko (German, 19??–19??) was another expert on titanium and advanced metal alloys in Germany during World War II. After the war, he came to the United States as part of the Paperclip program.

Carl Josef Bayer (Austrian, 1847–1904) developed a practical industrial process for extracting aluminum metal from the mineral bauxite.

A. Beerwald (German, 19??–19??) developed very lightweight magnesium alloys for aerospace vehicles in Germany during World War II.

?? Berblinger (German, 19??–19??) was a metallurgy expert in Germany during World War II, and was employed or at least sought by the U.S. Army's Fort Monmouth, New Jersey laboratory after the war.

Carl Berg (German, 1851–1906) developed and supplied aluminum alloys for the first rigid airships that were made by David Schwarz and Ferdinand von Zeppelin (pp. 1644–1645).

Franz Bollenrath (German, 1898–1981) was an expert on metallic materials and structures who worked at the Technische Hochschule Berlin before World War II, Sonthofen on secret military work during the war, and the Technische Hochschule Aachen after the war.

August Borsig (German states, 1804–1854) was a metal manufacturer and industrialist who founded the Borsig company, which later became Rheinmetall-Borsig.

Hermann Bottenhorn (German, 19??–19??) was an expert on aircraft metallurgy in Germany during World War II, and continued his work at Wright Field, Ohio, after the war.

?? Bruche (German, 19??–19??) conducted work on metallurgy during World War II. After the war, he either worked for or at least was actively sought by the U.S. Army's Fort Monmouth laboratory.

Robert Bunsen (German, 1811–1899, p. 433) discovered that pure aluminum could be produced using electrolysis.

Otto Dahl (German, 19??–19??) developed metal alloys at Siemens & Halske during World War II.

Walter Dawihl (German, 1904–19??), the head of Osram's research department, developed novel hard metal alloys and hard coatings for metal tools during World War II. After the war, he was extensively interrogated by Allied investigators, and he wrote a widely used handbook on hard metal alloys and coatings.

Ulrich Dehlinger (German, 1901–1981) developed the theory of dislocations in metals at the University of Stuttgart, where he worked from the 1920s to the end of his career.

Bernard Dirksen (German, 19??–19??) conducted research on metallic materials and structures in Germany during World War II and at Wright Field, Ohio, after the war.

Hans Fischer (German, 19??–19??) was an expert on the cold processing of steel in Germany during World War II. After the war, he continued his work at the Aberdeen Proving Ground in Maryland, along with Heinrich Kopp and Ludwig Schuster.

Richard Glocker (German, 19??–19??) was a metallurgist in Stuttgart during World War II and worked at the U.S. Army's Fort Monmouth laboratory after the war.

Max Hansen (German, 1901–1978) was another expert on titanium and other metal alloys who came to the United States after the war, before eventually returning to (West) Germany. In her history of titanium research, Kathleen Housley wrote [Housley 2007]:

> The research at Armour [Research Foundation in Chicago] was led by Max Hansen, a German metallurgist and world-renowned expert on phase diagrams whose doctoral work had been paid for by Kroll, who considered Hansen's intelligence to be worth the gift of tuition. Hansen had taken the position of professor of metallurgy at Illinois Institute of Technology after the war. Harold Kessler, who worked with Hansen at Armour, recalled the circumstances of his appointment. "As the war was coming to an end, the British were aware of Max, for he had published many important papers on aluminum alloy development as well as his pioneering work on binary alloy phase diagrams. They smuggled him out of Germany to England just as the Russians were coming to get him with the intention of smuggling him to the U.S.S.R. Then the position at Armour opened up and he came to the States." Like his mentor Kroll, Hansen was a gentle, soft-spoken man venerated by his co-workers who included besides Kessler, Donald McPherson, William Rostocker, Frank Crossley, Raymond van Thyne, and C. Robert Lillie. "He set a personal example of professional excellence and integrity," remembered Kessler. "He taught, counseled, and cajoled his students and colleagues toward better, more productive careers, and inspired an esprit de corps in all those with whom he

> worked." According to Margolin, the esteem in which Hansen was held bordered on awe. "On phase diagrams, Hansen was the authority. With a phase diagram, you do it, but a lot of times, there are things wrong because you don't fully understand what you are doing, and you have to guess. It is a very time-consuming process. I remember that Hansen did the titanium-aluminum diagram in three months. I was absolutely amazed." [...] Armour had several contracts with industry and branches of the Armed Forces, particularly with Wright-Patterson Air Force Base where metallurgical research was under the direction of Dr. H. K. Adenstedt. A close friend of Hansen's, Adenstedt had worked with him in the German aluminum industry and had come to the United States as part of the round-up of German scientists.

F. Heimes (German, 19??–19??) conducted metallurgy research at Neckersulm during World War II. After the war, he either worked for or was sought by the U.S. Army's Fort Monmouth lab.

Wilhelm Carl Heraeus (German, 1827–1904), who came from a generations-long family pharmacy, developed a high-temperature smelting process to produce pure platinum in 1856. To make use of that process, he founded and managed the Heraeus metallurgy company in Hanau. The company was subsequently run, and its metallurgical processes improved, by this founder's son Wilhelm Heraeus (German, 1860–1948) and then grandson Wilhelm Heinrich Heraeus (German, 1900–1985), both of whom were Ph.D. scientists.[17]

Albrecht Herzog (German, 19??–19??) worked on metallic materials and structures in Germany during World War II and at Wright Field, Ohio, after the war.

Albert Kochendörfer (German, 19??–19??) and Werner Köster (German, 1896–1989) conducted metallurgy research at Stuttgart during World War II. After the war, they either worked for or were sought by the U.S. Army's Fort Monmouth lab.

Heinrich Anton Karl Kopp (German, 19??–19??) was another expert on the cold processing of steel in Germany during World War II. After the war, he continued his work at the Aberdeen Proving Ground in Maryland, along with Hans Fischer and Ludwig Schuster.

?? Kornetzke (German, 19??–19??) conducted metallurgy research at Heidenheim during World War II. After the war, he either worked for or was sought by the U.S. Army's Fort Monmouth lab.

A. Krisch (German, 19??–19??) developed new processes for manufacturing and fabricating steel stock and components during World War II. He appears to have worked for the United States after the war.

William Kroll (1889–1973) was born in Luxembourg but was educated and worked in Germany. Like Anderko, Adenstedt, and Hansen, he developed titanium and other advanced metal alloys in Germany during World War II and in the United States after the war.

Friedrich Krupp (German states, 1787–1826) founded the Krupp steel company and developed new casting techniques. Alfred Krupp (German, 1812–1887) inherited and expanded the Krupp steel company. He and others at the company developed greatly improved methods of fabricating steel components ranging from train wheels to cannon barrels.

---

[17] https://www.heraeus.com/en/group/about_heraeus/corporate_history/corporate_history.html

Richard Küch (German, 1860–1915) was the head scientist at Heraeus in the years around 1900. Küch developed alloys and processes for producing them, as well as a high-temperature process to produce quartz of exceptionally high purity and quality.

Ernest Kugel (German, 19??–19??) was an expert on aircraft metallurgy in Germany during World War II, and continued his work at Wright Field, Ohio, after the war.

Reinhard Mannesmann (German, 1856–1922) inherited and expanded the Reinhard Mannesmann steel company along with his brothers. He developed a number of new methods of fabricating steel stock and steel components.

Günther Möhling (German, 19??–19??) obtained his Ph.D. in Germany in 1928 with a thesis "Über Optisch Aktive Arsenverbindungen" ("On Optically Active Arsenic Compounds"). He appears to have moved to the United States in the 1930s. He ended up in charge of metallurgical development at the Allegheny Ludlum Steel Corporation, where he introduced German metallurgical methods and alloys and began receiving U.S. government funding.[18] He also appears to have reaped a windfall of additional metallurgical information from Germany when World War II ended. At Allegheny Ludlum, Möhling copied Tinidur (renamed A-286), Cromadur (renamed AF-71), and other German alloys, as well as German metallurgical methods such as vacuum melting. Metallurgist Art Kracke briefly alluded to the early history of these technologies in Germany and their transfer to the United States during and after World War II [Kracke 2010]:

> Breakthrough Events in Superalloy Processing
>
> - 1905: W. von Bolton consumable electrode arc melted tantalum in a cooled copper crucible under a low pressure of argon. [See p. 967.]
> - 1917: W. Rohn first melted nickel alloy in a vacuum resistance heated furnace.
> - 1923: Heraeus Vacuumschmelze A.G. founded to operate vacuum furnaces.
> - 1926: Two VIM furnaces in operation melting 80 Ni 20 Cr and 65 Ni 15Fe 20 Cr for thermocouples and denture alloys.
> - 1950: Dr. Möhling melts first large heat, ten tons, vacuum induction melt of aluminum and titanium containing strengthened superalloy at Allegheny Ludlum Steel laboratory in Watervliet, NY.
> - 1952: Special Metals Co., New Hartford, N.Y. produces the first production heat of Waspaloy in a 6-lb furnace for Pratt & Whitney J48 turbine engine blades
> - 1953: First production vacuum arc remelting of superalloys by Allegheny Ludlum Steel in their Watervliet, NY laboratory.
>
> [...] Vacuum melting was first performed in 1916 in Hanau, Germany by Dr. Wilhelm Rohn and W. C. Heraeus in a vacuum induction furnace of their design. Their work,

---

[18] *Automotive News*, 30 April 1945, p. 57, cols. 3–4. https://chroniclingamerica.loc.gov/lccn/77618337/1945-04-30/ed-1/seq-57/

> focused on steels, led to the development of clean steels that enabled aircraft engine technology including the development of turbine engines for military aircraft used in WWII.
>
> In 1945 a small vacuum furnace was built at NACA to melt high temperature alloy samples for evaluation. [...]
>
> The following comment made by Rudolph Thielemann in 1967 in a presentation to the European Investment Casters Federation is a testimonial to the role vacuum melting played in the success of superalloys and their role in gas turbines. “Since the early work on the exhaust gas driven turbosuperchargers, a great deal of progress has been made in developing high temperature alloys for critical gas turbine applications. In this effort, the development of new processes and techniques for melting, consolidating and casting the alloys has been very important. The introduction of the (vacuum) melting furnace has furthered the metallurgical progress in the alloy development more than any other single factor.”

Hermann Nehlsen (German, 19??–19??) was an expert on aircraft metallurgy in Germany during World War II, and continued his work at Wright Field, Ohio, after the war.

Wilhelm Rohn (German, 1887–1943) was the head scientist at Heraeus after Richard Küch. In 1913 he invented vacuum melting, a technique that enabled the production of advanced, high-temperature alloys. Rohn and Heraeus developed and used the technique for commercial applications from then through World War II.[19]

Franz Sauerwald (German, 1894–1979) developed very lightweight magnesium alloys for aerospace vehicles in Breslau during World War II.

Ludwig Schuster (German, 19??–19??) was another expert on the cold processing of steel in Germany during World War II. After the war, he continued his work at the Aberdeen Proving Ground in Maryland, along with Hans Fischer and Heinrich Kopp.

Hugo Stinnes (German, 1870–1924) ran the Stinnes steel company, which developed new metal alloys and custom metal components for new technological applications.

Fritz Thyssen (German, 1873–1951) was a metallurgist who inherited, expanded, and ran the Thyssen steel company, which developed a variety of new alloys in the early twentieth century.

Carl Auer von Welsbach (Austrian, 1858–1929, pp. 435 and 966) discovered praseodymium (1885), neodymium (1885), ytterbium (1905), and lutetium (1905). He also invented the gaslight mantle (1885), osmium wire (1890), metal filament incandescent lamps (1898), and the flint metal lighter (1903). In order to commercialize his discoveries and inventions, he founded the companies of Auergesellschaft, Treibacher Industrie, and Osram.

In 1906, Alfred Wilm (German, 1869–1937) invented the Duralumin aluminum alloy (aluminum with small amounts of copper, magnesium, manganese), which has been widely used in the aerospace industry ever since. He also discovered age hardening for aluminum alloys and other metals in 1901.

---

[19] https://vacuumschmelze.de/unternehmen/firmenhistorie

Friedrich Wöhler (German, 1800–1882, p. 432) discovered and purified aluminum.

Despite the wartime shortages, by 1945 metallurgy was so advanced in the German-speaking world that Allied countries seized large quantities of information and scientists, and even complete factories, to improve the state of metallurgy in their own countries (Figs. 3.187–3.188).

For example, in September 1945, R. P. Linstead and T. J. Betts, the British and American chairs of the Combined Intelligence Objectives Subcommittee (CIOS), listed a number of important German innovations in metallurgy [AFHRA A5186 electronic version pp. 904–1026, Ch. 4, pp. 52–53]:

> In the field of ferrous and nonferrous metallurgy the following discoveries are worth recording:
>
> 1. A new flux for welding magnesium.
>
> 2. A hard magnesium coating obtained by anodizing aluminum oxide which had many industrial and armament applications.
>
> 3. Refinements in the process of continuous casting. This casting was done into a tank of water rather than an open pit. The method employed a small mould which resulted in many economies of production.
>
> 4. The use of chemicals in the grain refining process in heating magnesium for casting. This process, used in the production of high quality magnesium, permitted achievement of equal quality by using a temperature 100^oC below that employed in the conventional process.
>
> 5. The electric smelting furnace developed by Siemens and Halske. This resulted in the production of pig iron with little coke, a process with distinct advantages when coke supplies are limited and cheap hydro-electric power abundant. A further advantage is the reduction of the sulphur content in pig iron.
>
> 6. Improved hard cemented carbide for use in cutting tools.
>
> 7. German development and use of drawn steel cartridge cases. Steel cartridge cases were designed for a wide range of calibers ranging from small arms to large artillery pieces. Steel cartridge cases have the obvious advantages of saving critical materials.

As a more focused example, BIOS 925, *Tungsten Carbide Research in Germany*, p. 3, discussed German innovations in metal hardening that Allied countries wanted to copy (see also BIOS 1076):

> This report contains the results of a detailed interrogation of Dr. [Walter] Dawihl who was head of Osram's Research Department. By agreement with Krupps this Laboratory carried out all hard metal research on behalf of the Widia organisation and as such was the most important Hard Metal Research Laboratory in Germany.
>
> The report gives a general survey of the Research Programme of the Laboratory during the war years and traverses the latest theories on the fundamental metallurgy of hard metal as developed by Dr. Dawihl.

> It describes his experiments to relate the practical performance of hard metal with metallurgy and discusses the effect of crystal formation and shape on the physical properties.
>
> A technique of coating steel with a thin hard metal skin is described and the composition of the metal is given.
>
> Descriptions of the processes of making boron carbide and titanium boride are given and a very brief resume of the work done on sintered iron and steel.
>
> Part III deals with the practical application of Laboratory Research to commercial practice and gives brief descriptions of methods of manufacture, specifications and a detailed costing of each operation.
>
> Appendix I is probably the most valuable portion of the report as it contains a list of Reports issued by the laboratory, copies of which are in our hands. They are listed by H.E.C. numbers, title and number of pages and diagrams.
>
> Appendix II is a description of making tungsten carbide in an electric arc furnace of novel design by D.E.W., Krefeld.
>
> Appendix III is a drawing of a continuous rotary tube furnace for carburising.

For further examples of how advanced German and Austrian metallurgy technologies were transferred to Allied countries after the war, see pp. 4090– 4152. See also the large number of metallurgy-related BIOS ER, BIOS, BIOS Misc., BIOS Overall, CIOS ER, CIOS, FIAT, *FIAT Review*, JIOA, NavTecMisEu LR, and NavTecMisEu reports in the Bibliography.

American metallurgists Charles R. Simcoe and Frances Richards provided a glimpse of how German-speaking scientists and methods were utilized to create advanced metal alloys in the postwar United States [Simcoe and Richards 2018 pp. 145, 147–148]:

> Titanium was on its way to becoming the aerospace metal that its promoters had hoped it would be. Then an earthquake shook both the aerospace industry and titanium. The Secretary of Defense, Charles Wilson, formerly of General Motors Corporation, announced a decision to base the defense of the country on missiles rather than on manned aircraft. The accompanying reductions and cancellations of contracts rocked the industry. [...] The reduction in aircraft and engine production caused a near-total collapse of the titanium market. This most promising of metals for the postwar era, which had received an estimated $200 million in government support, was in serious danger of extinction by the very DOD that had brought it into being. [...]
>
> The changes in the titanium industry had changed the career paths of many of the individuals selected as founders. William Kroll returned to Europe to enjoy his retirement years in Brussels. Max Hansen left ARF to accept a high-level post in the metals industry in Germany. In 1958, Hansen and Kurt Anderko, another German who worked with Hansen at ARF and who had returned to Germany with him, published a monumental second edition of the "Constitution of Binary Alloys." [...]

> By the late 1950s and early 1960s, the major research and development support for titanium by the government had ceased. The founders, as well as the younger researchers, were forced to find other areas of research or move on to other employment. [...]
>
> One significant development in the 1960s was the building of the SR-71 Blackbird military reconnaissance plane with a speed capability of Mach 3. The SR-71 was an all-titanium aircraft manufactured with Ti-6Al-4V and a new alloy, Ti-13V-11Cr-3Al. Another early 1960s attraction was the interest in a supersonic transport plane. It would have been an all-titanium aircraft that was planned to compete with the European-made Concorde. It was planned to fly at nearly Mach 3 and would have used large amounts of titanium per plane for a planned 200-plane fleet. The program was cancelled by Congress in 1971.

Thus German-speaking scientists were apparently responsible for the heat-resistant, strong, lightweight titanium alloys that made the SR-71 Blackbird spy plane and the XB-70 Valkyrie bomber (pp. 1750, 1754–1755) possible, and that would have made possible a fleet of Mach-3 passenger aircraft. Unfortunately the United States lost interest in such technologies, and those German-speaking scientists retired or found employment in other areas.

Much more archival research should be conducted to clarify the direct (via invention and development) and indirect (via technology transfer) contributions of German-speaking scientists to the methods and applications of metallurgy.

Heinrich Adenstedt (1910–1991)

FEATURE

Governmental, scientific and industrial agencies as well as engineering societies and individuals are invited to submit papers believed to be of general interest to the readers of the TECHNICAL DATA DIGEST, for publication in this section. Manuscripts should be prepared in the conventional manner and addressed to CG, Air Materiel Command, Wright-Patterson Air Force Base, Dayton, Ohio — Attn: Air Documents Division, MCIDXS5.

GERMAN METHODS IN DEVELOPING TURBINE-WHEEL BLADES FOR THE JUMO-004

HEINRICH K. O. ADENSTEDT

Analysis Division, Intelligence Department, Air Materiel Command

Designs

The turbine wheel of the Jumo-004 measures approximately 700 mm (27.49 in.) in total diameter, and contains 61 blades, each approximately 110 mm (4.33 in.) in length. The blades were mounted on the wheel and fixed by two riveted pins, while the wheel was flanged to the shaft and bolted with stud bolts. Figure 1 shows a section of the turbine wheel.

For the blade attachment two designs were used: (1) the so-called Junkers attachment as shown in Fig. 2, and (2) the so-called Lamelle base, developed by the Allgemeine Elektricitaets Gesellschaft (General Electric Co.), Berlin, as shown in Fig. 3.

Materials

The construction of the first jet engines was accomplished without considering the scarcity of materials, because the initial work required operational safety. For this reason the entire wheel was made from Krupp's top-grade, heat-resistant steel, P 193 (later called "Tinidur"). The composition of Tinidur can be seen in Table I. The original steel used had a carbon content of 0.4%, but this was immediately replaced by a steel with 0.15% carbon. Cobalt steels, although better in creep-resistance properties, could not be used because of a shortage of this material in Germany.

At first the blades were machined from steel rod, 45 mm by 45 mm (1.77 in. by 1.77 in.) and later from die-forged material. The wheels were machined from rough blanks. Prior to 1944 blades were made of Tinidur, which was later replaced by Cromadur (Table I).

The disk material was then changed over to a heat-treatable composition, after it was established that the temperatures were lower than 600°C (1112°F) in the turbine wheel. At first the principal steels used were MC 120 from DEW (Krefeld and FKDM 10 from Krupp at Essen (Table I). Later, when more accurate temperature measurements with thermocolor paints were made, the alloy content (Mo and Cr) of the disk material was further reduced, and Flw 1310 steel was used. This material was employed in a special heat-treated condition, 1310.9 (Table I), which was developed particularly for this purpose. Heat-treatment consisted of heating to about 1000°C (1832°F) and quenching in a warm-oil bath or salts. The temperature of the salt bath was about 350°C (662°F). The purpose of this heat treatment was to produce bainite (at least in the rim) to assure the best high-temperature properties. In the meantime other steels which had physical properties falling between Flw 1310.9 and FKDM 10 (e.g., FKM 10, Flw 1456.9 and Flw 1620.9) were tried.

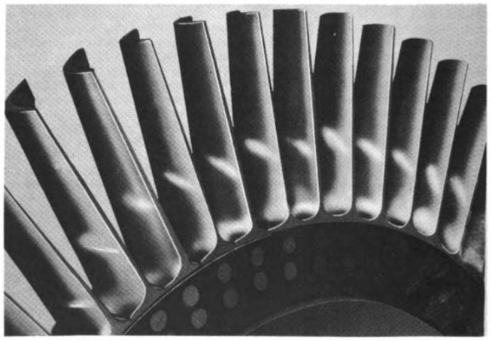

Fig. 1—Section of the Jumo-004 Turbine Wheel.

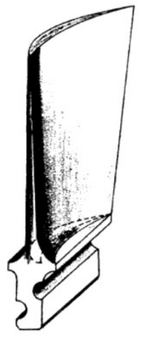

Fig. 2—Junkers Attachment.

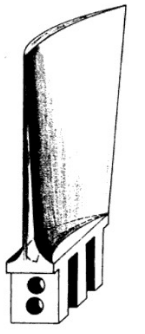

Fig. 3—Lamelle Base.

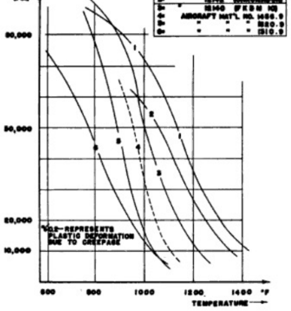

Fig. 4—Creep Resistance of Various Steels.

The pin material was changed from Tinidur to FKDM 10, FKM 10 or Flw 1456.9. A molybdenum-free steel, e.g., 1310.9, could not be used for the pins. This will be explained later. The creep resistance of the most important of these steels will be found in Fig. 4.

Difficulties with Turbine Disks

In the case of the first austenitic disks made of Tinidur steel, surface tears were experienced, which indicated the difficult forgeability of this titanium-bearing steel. Some of these tears were so deep that it became necessary to discard the disks; the remaining disks were used satisfactorily. During operation no difficulty occurred with them as there were only about ten disks that were made from this material.

From the disks made of heat-treated steel two acute failures occurred. On one disk of MC 120, which still had the old Junkers attachment, several attaching pivots broke on the grooves of the pins without elongation. An investigation revealed that on the same jet, cooling for the disks did not prove effective, and the disks had become overheated. Therefore, the stress of 28 kg/mm^2 (39,800 psi), effective at this place, caused a creep break.

A wheel of material Jumo N 12141 exploded completely. Investigation proved that a quenching crack had occurred, which had not been discovered by the inspectors.

Final Acceptance for the Wheels

The disks were inspected and tested in the steel mill in the usual way by the inspector representative of the Reichsverband Deutscher Luftfahrt Industrie (RDLI). There was no special acceptance specification. Each of the first few disks was forged with a prolongation, which was used as a test coupon. Determinations were made of ultimate strength, yield strength, elongation, impact resistivity and creep rates. In mass production, all of these tests could not be carried out, which limited inspection to magnaflux and hardness tests. On the basis of magnaflux tests, a small percentage of the disks was always scrapped because of tears.

Figure 3.178: Heinrich Adenstedt developed and used advanced metal alloys in Germany during the war and in the United States after the war [Adenstedt 1948]. Throughout his career, he worked very closely with jet/helicopter/tank engine designer Anselm Franz (pp. 1381, 1739–1740).

Temperature Measurements of the Disks

At first, temperature measurements were made with thermocouples. In using these measurements, the wheel was made stationary and the blades were heated to the correct temperature by means of a ring burner, while the other testing apparatus cooled the disk to a ratio as if it were in operation. These tests could give only approximate results, and were later replaced by thermocolor paints which determined the temperature of the wheel during operation. This test was made as follows: Several small strips along different radius vectors of the disk were sand blasted and then sprayed with aluminum by the Schoop procedure. Onto the white rough aluminum surface a suitable thermocolor paint was applied by brush. On this prepared surface a strip of asbestos and a sheet-metal strip of 18-8 steel were screwed tightly against the disk. This arrangement, which proved satisfactory, can be seen in Fig. 5. The asbestos covering prevented the thermocolor paint from being affected by external heat conditions caused by surrounding air. This insured accurate wheel temperature determinations by the thermocolor paints. On the white aluminum surface the change of color was easily visible and the few isolated strips affected very little the cooling of the disk through the surface. (Only 10% of the disk surface was covered by the strips). These investigations proved an operational temperature of 400°C (752°F) at the lower end of the blade base and 220°C (428°F) in the center of the disk. These values gave the basis for the material change to Flw 1310.9. Later the temperature measurements were repeated on hollow-blade wheels in a somewhat different manner. The thermocolor paints were placed inside of hollow drilled screws of 18-8 steel; the hole was then closed with a piece of sheet metal. The screw prepared in this way was driven into the disk at the desired place for temperature measurement. After the test the screw was opened, the paint was sifted on paper and spread out with a knife; the color change was easily visible.

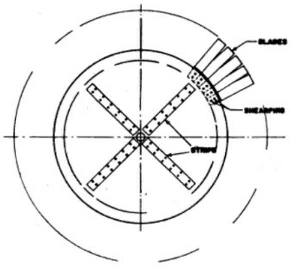

Fig. 5—Location of Strips for Temperature Measurement on the Wheel.

Difficulties with Shear Pins

During mass production, no pin failures were caused by shear. Two test wheels were constructed with pins of steel Flw 1267.9 (Table I). In the case of one wheel, after 92-hr operation the pins sheared off, and one blade flew off. Because of this failure, the pins were then made of a molybdenum steel (Flw 1456.9, Jumo N 12140 or 12141). Flw 1310.9, which has a higher creep resistance than 1267.9 by about 30°C, was not used for the pins, because the 30°C advantage was considered insufficient. Special final acceptance was not prescribed for the pins.

Difficulties with the Blades

The observed blade breaks can be placed into two categories: (1) fatigue breaks and (2) creep breaks. These are discussed specifically below.

1. Fatigue Breaks

This type of break was observed almost exclusively at the beginning of turbine-blade development, with fractures occurring at different points in the lower part of the blades. Using the old Junkers attachment (Fig. 2), the weak place proved to be the upper shear-pin hole. Fatigue fractures were experienced in a number of blades at this particular place. This condition was improved by employing a different method of fastening. The diameter of the upper pin was decreased, and the outer radius (R) on the wheel base and on the pivots was decreased as shown in Fig. 2. Also on the lamelle base (Fig. 3) several fatigue breaks were recognized - in the lamelles themselves and in the base plate. This necessitated a heavier base plate. The fatigue breaks in the blades themselves occurred mostly at the lower part of the blade length.

The temperature and velocity distribution behind the nozzle diaphragm were found to be not uniform, which led to excitations of the blades, causing the fatigue breaks. At full power there are 145 rps x 6 (combustion chambers) = 870 stress cps. This figure corresponded to nearly fundamental natural frequency of the blades during operation. When cold, the latter was 900 - 950 cps, but this value is increased during the operation by centrifugal force, and decreased by modification of the material (change of modulus of elasticity). In all, a decrease of 8% was calculated.

The breaks appeared partially after operation of 50 hours or more, which corresponds to over 10^8 c of load, and therefore means a very long working time. After the lapse of such a long time, no breaks should be expected if we consider a Woehler curve. The explanation is the very sharp natural frequency of the blades, effected by a small degree of damping. Therefore a small rpm fluctuation gives a great reduction of the stresses in the critical blades. All these cycles with reduced stresses do not count in our consideration of the Woehler curve.

As a remedy, the natural frequency was increased about 100 cps by more acutely conical forming of the blades, and by a 1-mm reduction of the length. Further, a 100% frequency test was prescribed, whereby the natural frequency was required to be over 1000 cps. Blades with too low natural frequencies were saved by reworking (material machining of the inner side of the blade in the upper quarter of the length).

The frequency test of the finished wheel was carried out by an acoustical method. The 61 blades were agitated at the head end with a violin bow, and the arising tone was compared with a normal known tone. The normal tone was created by a set of tuning forks consisting of prongs with a natural frequency (with an interval of 25) of between 950 and 1150 cps. The forks were agitated by means of an eccentric, and the tone was reproduced by means of a coil, an amplifier, and a loud speaker. All forks could be simultaneously agitated, and the desired tone could be heard by pressing the proper button. Figure 6 shows the arrangement schematically. In this way it was possible to test a wheel in a few minutes, and the natural frequencies of the different blades could be determined within limits of less than 25 cps.

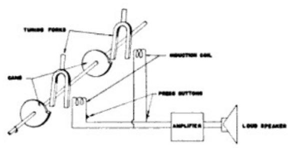

Fig. 6—Schematic Diagram of Frequency Generator.

After the increase of the blade frequencies and after the introduction of the preceding acceptance test, practically no fatigue breaks occurred.

2. Creep Breaks

Creep breaks occurred particularly in the upper part of the blades. These were mostly intergranular and without deformation. As such breaks practically marked the life limit of the wheel, great effort was made to avert them as long as possible. This was done in collaboration with the factory of Krupp, the AEG turbine factory, and the branches of the Junkers concern.

From the breaks which occurred and from the creep-rupture tests, it was concluded that Tinidur is not very ductile at elevated temperatures when subjected to creep conditions; that when creep progresses to about 1.5%, a brittle fracture will occur, and that the ultimate elongation caused by creep is further reduced by: (1) large grains, (2) notches (grinding marks, too sharp edges, etc.), (3) inclusions which cause notch effects (oxides, segregations, etc.), and (4) melting influences, which could not be explained in detail (gas content, melting procedure, etc.).

If these irregularities occur, premature failures are to be expected, especially if, by the tilting of the blade (caused by manufacturing inaccuracy) or by thermal shock, a stress raiser occurs locally. The stress raiser, caused by tilting of the blade, is dependent upon the direction of the inclination of the blade outwards of its gravity line. This stress increase can be very important. Numerical values can be given only when exact drawings of the blades are available. A thermal shock (caused by sudden heating or cooling of the blades during starting or stopping) may overstress the extreme edges of the blades. It was found that the number of cycles of starting and stopping is very important for the life of the blades. In particular, coarse-grain blades were very sensitive to thermal shock. In the Jumo-004 a more elastic type of controller system minimized excessive thermal shock.

Control of the Blades

The specifications prescribed for the control of the blades were:

1. Control of the Melt - The chemical composition had to be as prescribed in the standard Jumo N 12139; especially the titanium content had to be precise. Difficulties in the chemical-analysis procedure which existed at first in the titanium determination were removed. In the steel mill, the basic suitability of the melt was proved (RDLI Control, quality test, precipitated hardening).

2. Forging Procedure - The forging was inspected at each place in order to facilitate the procedure. Between the various steps of forging, macro-etchings were made. Rod sections with center segregation were rejected; half-finished rough forgings with surface tears were ground out or rejected. Figure 7 depicts in both views A and B two characteristic troubles of Tinidur. View A shows a surface crack caused by titanium oxide aggregation, and View B a preforged sample with opened head due to central segregations. The forging furnaces were temperature-controlled and the various forging dies were adapted in such a way that the end deformation was greater than 15%. By this procedure at 1080°C (1976°F) end forging temperature, good rough forgings with suitably small grains were obtained. The rough forgings were random tested for grain size by surface grinding the head of the blade (Krupp Company's system).

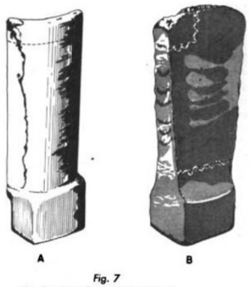

Fig. 7
A—Forging with a Surface Crack.
B—Preforged Sample with a Center Crack.

3. Testing the Finished Blades - The finished blades were all macro-etched before the end polishing, and then, by means of a magnifying glass, inspected by experienced workers for surface tears, large grains, segregations, and aggregation of titanium oxides. Acceptance specifications were determined by reference to photos and standard parts. By means of a special marking procedure which made it possible to recognize the particular steel mill, the melt number, and the forging manufacturer of the respective blade, it was possible to publish a monthly reject report from Dessau. This report was important for the steel mills and for the forges, because especially bad melts and bad forgings could immediately be traced. Ultimately 80 percent of the blades were found to be good.

4. Length Polishing - The surface of the blades was length ground and length polished in order to erase all transverse grinding marks.

5. Control of Tilting - After the blades were mounted, a special measuring procedure was provided for keeping the blades erect and for preventing tilting.

6. Frequency Control - Finally, the frequency test was made as described above.

7. Operating Life - The wheels were permitted to run 25 hours; then the blades were tested at random for hardness on the small phase, which is on the exhaust side of the blades. If the hardness of the entire length of the blade was higher than 200 Brinell, the blades were again length ground, and eventually notches were removed. The wheel was then operated for another 25 hours. The total time of operation was inscribed on the wheel by means of number stamps. It was the intention to continue this service to 100-hr total operation time, and then to replace the blades.

Up until the end of the war, only a few solid-blade wheels had reached this total operation time. Since 1944, the hollow blade has replaced the solid blade.

OFFICE OF TECHNICAL SERVICES

Substitute heat- and creep-resistant alloys were used successfully by the Germans during the war in the construction of gas turbines and jet propulsion engines, according to a British report now on sale by the Office of Technical Services, Department of Commerce. The Germans developed the substitutes to cope with shortages of nickel, tungsten, molybdenum, and chromium.

The report, based on visits to plants in Germany and Austria, was prepared by a team of investigators for the British Intelligence Objectives Sub-Committee.

Although German manufacturers produced no austenitic alloys equal to the best available in Allied nations, they did discover some ferritic alloys with satisfactory creep strengths up to about 600 degrees Centigrade, the report states. These strengths, however, were exhibited mainly in inconclusive, short-time tests.

The use of substitute alloys necessitated a great reduction in maximum temperature for the turbine blade and disc and also resulted in new designs to permit cooling both blade and rotor. The design of a successful hollow air-cooled blade led the Germans to place greater emphasis on the fabricating qualities of the alloys, particularly on their ability to be worked in sheet form and to be welded. The need for cooling somewhat offset the gain in turbine performance achieved through higher gas temperatures, according to the report.

The report describes comprehensively the composition and the heat treatments of the various alloys developed, and the methods and machines used for testing them. It also includes perspective and cross-sectional drawings of air-cooled blades; tables and graphs showing yield, tensile-breaking, and creep strengths of the alloys, as well as their tempering, forging, and annealing, temperatures.

Orders for the report (Report on Visit to Germany and Austria to Investigate Alloys for Use at High Temperatures; PB-28557; photostat, $6; microfilm, $2; 89 pages) should be addressed to the Office of Technical Services, Department of Commerce, Washington 25, D. C., and should be accompanied by check or money order, payable to the Treasurer of the United States.

Figure 3.188: Large amounts of information, materials, and scientists involved in work on advanced metallurgy were transferred to other countries after World War II [NARA RG 40, Entry UD-75, Box 3, Folder Press Releases].

3.9 Other Creations in Chemistry

German-speaking scientists made many other important discoveries and inventions in chemistry. This section covers just a few examples, including:

3.9.1. Chromatography

3.9.2. Colloids

3.9.3. Synthetic lubricating oils

3.9.4. Synthetic detergents and paper recycling

3.9.5. Chemical treatments to make fabrics resistant to fire, water, stains, and wrinkling

3.9.6. Firefighting chemicals

3.9.7. "Superglue"

3.9.1 Chromatography

Chromatography is a technique for separating molecules of different sizes that are initially mixed together, based on the fact that they will diffuse at different rates through wet paper, capillary tubes, or other solid, liquid, or gaseous materials. German-speaking scientists developed the general approach of chromatography as well as most of its specific implementations [Ettre 2001; Goppelsröder 1861, 1901; Runge 1850; Schönbein 1861].

Friedlieb Ferdinand Runge (German, 1795–1867) developed chemical spot tests on filter paper in the 1840s and first published his results in 1850, as shown in Fig. 3.189 [Runge 1850]. Runge's tests were essentially two-dimensional chromatography for separating a pool of molecules placed in the central spot into concentric rings of different types of molecules. (In 1820, Runge was also the first scientist to extract and identify caffeine.)

By exploring and harnessing that initial technique, Christian Schönbein (German states, 1799–1868) and his student Friedrich Goppelsröder (Swiss, 1837–1919) demonstrated one-dimensional chromatography methods both in filter paper and in capillary tubes in 1861 [Schönbein 1861; Goppelsröder 1861]. See Fig. 3.190.

Goppelsröder continued working to improve and to apply capillary-based chromatography for several decades, including using it to separate and analyze the colored pigments from plant leaves [Goppelsröder 1901]. See Figs. 3.191–3.193.

Raphael Eduard Liesegang (German, 1869–1947, Fig. 3.194) also developed and used improved methods of capillary and paper chromatography [Ettre 2001].

Building on the earlier work of Goppelsröder with the chromatography of plant pigments, Richard Willstätter (German, 1872–1942) developed improved methods for chromatography and used those to identify in detail the molecular structures of different types of chlorophyll and other plant pigment molecules (Fig. 3.194). For that work, he won the Nobel Prize in Chemistry in 1915 (p. 407).

Gustav Hertz (German, 1887–1975) invented gaseous diffusion enrichment and gas chromatography; he filed detailed patent applications on his methods in 1923 (Fig. 3.195). He continued to work on gas chromatography (as well as other projects) in Germany until 1945, and in the Soviet Union during the period 1945–1955. It seems likely that his work for those two countries involved using gaseous diffusion methods to separate uranium isotopes for nuclear weapons programs, although currently very little documentation from that work is publicly available.

Inspired by the pioneering work by Hertz, Erika Cremer (German, 1900–1996) began developing improved methods of gaseous diffusion and gas chromatography in the late 1930s and continued throughout World War II (Fig. 3.195). As with Hertz, it seems likely that her work involved using gaseous diffusion methods to separate uranium isotopes for the German nuclear program, though little documentation is currently available. Cremer continued to work on gas chromatography after the war, and is best known for her postwar demonstrations and publications on gas chromatography, including those with her student Fritz Prior (Austrian, 1921–1996) [Bobleter 1997].

See also pp. 3494–3640 for other work related to gaseous separation and gas chromatography.

3.9.2 Colloids

Figure 3.196 illustrates what a colloid is. As opposed to solutions of tiny particles that remain dissolved permanently (such as salt in water), or suspensions of large particles that eventually settle out (such as sand in water), colloids have medium-sized particles that can remain suspended indefinitely within a material (such as fat particles suspended in water as in milk). Some German-speaking scientists who made important contributions to the understanding and application of colloids are shown in Figs. 3.196–3.197.

Georg Bredig (German, 1868–1944) developed colloidal solutions of metals as catalysts.

Herbert Freundlich (German, 1880–1941) studied colloidal stability and coagulation.

Franz Kolb (German, 18??–19??) worked with colloids and invented plasticine modeling clay in 1890.

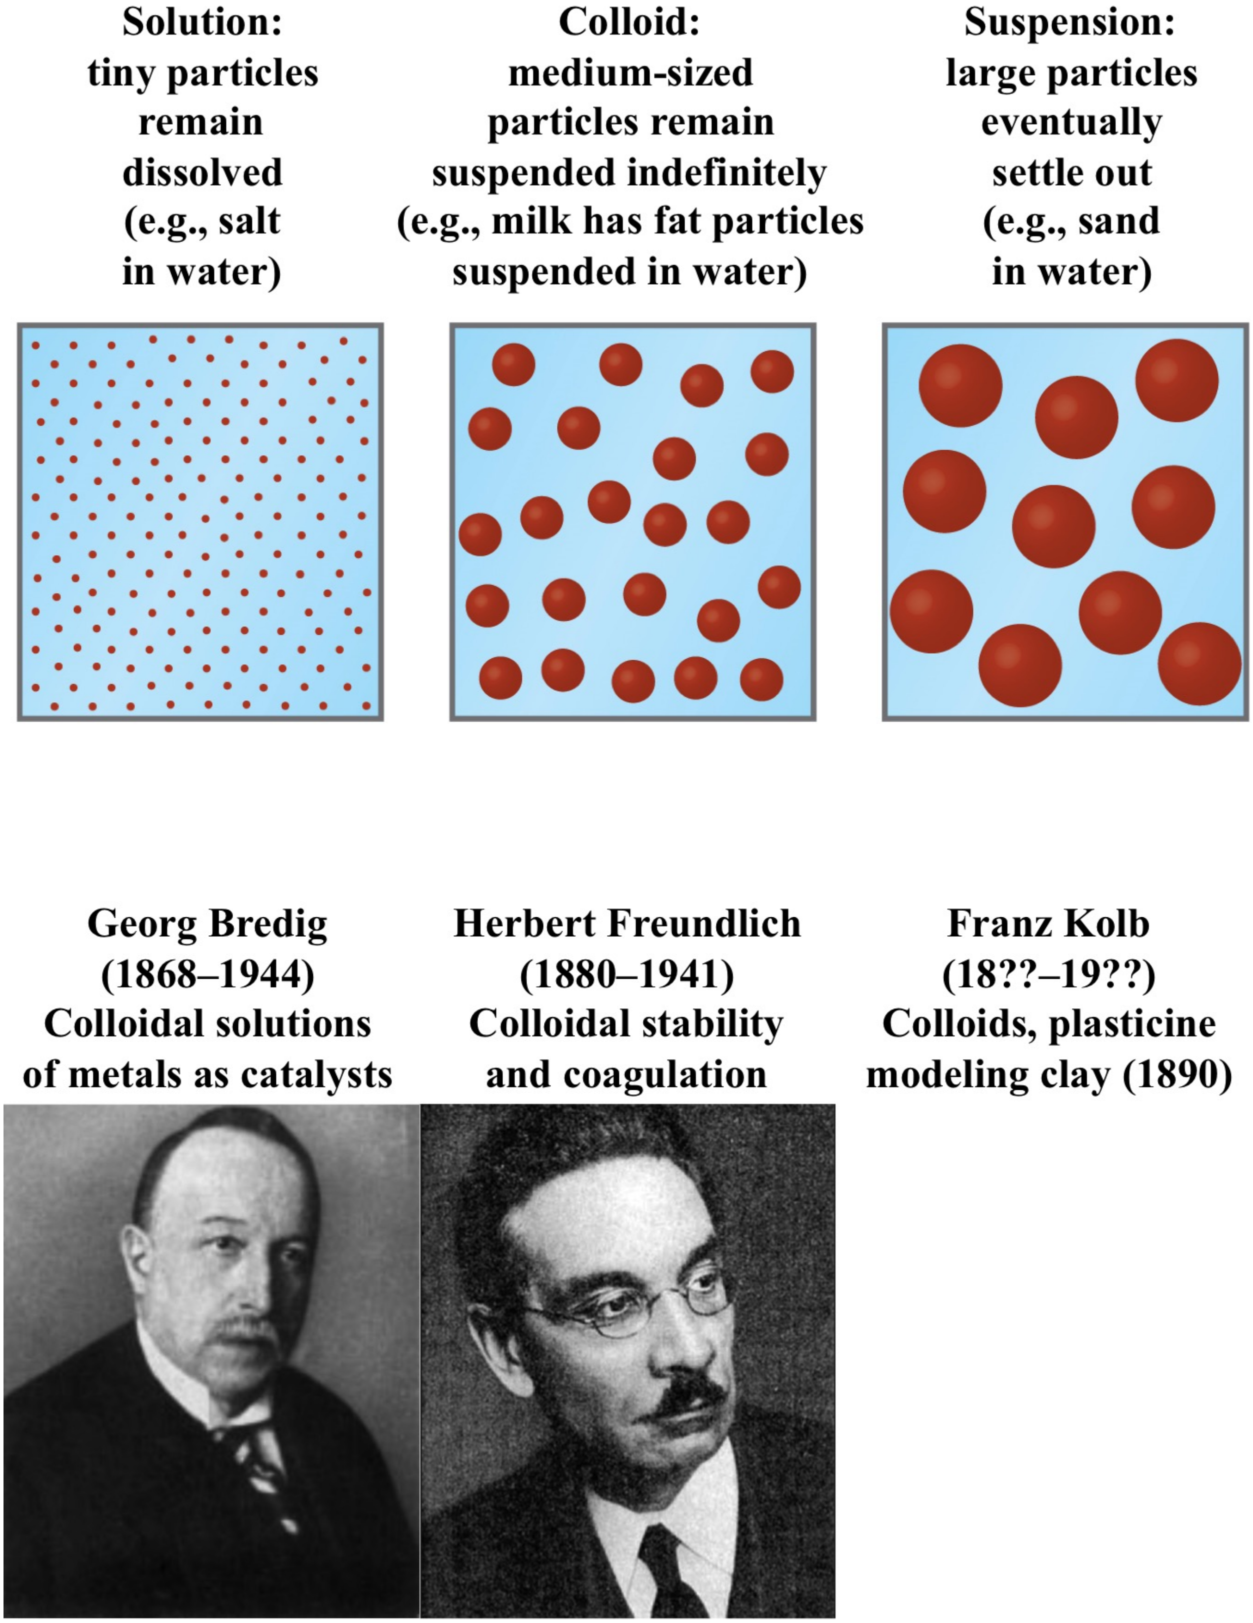
Robert Havemann (German, 1910–1982) conducted research on colloids. In 1936, he also invented the spectrophotometer, which is now a widely used instrument in biology and chemistry laboratories (p. 2307).

Carl Wilhelm Wolfgang Ostwald (German, 1883–1943) also did important work on colloids.

Hermann Staudinger (German, 1881–1965) studied colloids, macromolecules, and polymers. He found that many substances that had been regarded as colloidal clumps of small molecules were actually composed of macromolecules or polymers. For his discoveries, he won the Nobel Prize in Chemistry in 1953 (p. 474).

Richard Zsigmondy (Austrian, 1865–1929) made a number of important discoveries regarding colloids, and also developed synthetic food products. He won the Nobel Prize in Chemistry 1925 for his work on colloids. Professor H.G. Söderbaum, Secretary of the Royal Swedish Academy of Sciences, stated [https://www.nobelprize.org/prizes/chemistry/1925/ceremony-speech/]:

> Zsigmondy's work has quite simply been pioneering as regards the explanation of the mechanism of the coagulation phenomenon and also as regards the study of the structure of gels. [...]
>
> The brief review given here of some of the most important work of Zsigmondy is necessarily highly incomplete, if not to say fragmentary, but should surely suffice to show how it pioneered the way and opened up new regions in a field of research which had so far been difficult of access, a field which must be recognized as having the very greatest importance for human knowledge. Let us only remember in this connection that all manifestations of organic life are finally bound to the colloidal media of the protoplasm.
>
> This by way of motivation for the decision of the Academy of Sciences to award the Chemistry Nobel Prize for 1925 to Dr. Richard Zsigmondy, Professor of Chemistry at the University of Göttingen, for proving the heterogeneous nature of colloidal solutions and for the methods used which have laid the foundation of modern colloid chemistry.



Solution: tiny particles remain dissolved (e.g., salt in water)
Colloid: medium-sized particles remain suspended indefinitely (e.g., milk has fat particles suspended in water)
Suspension: large particles eventually settle out (e.g., sand in water)

3.9.3 Synthetic Lubricating Oils

During the period 1927–1945, Hermann Zorn (German, 1896–1983) led a large group at I.G. Farben Ludwigshafen that invented and mass-produced synthetic lubricating oils and additives [Jantzen 1996a, 1996b]. As a result of their work, Zorn and his coworkers filed a large number of patents worldwide; see Figs. 3.198–3.199 for some examples. Some of their patents were approved and issued in the 1930s, but many were not finally approved and issued until after World War II.

In addition to Zorn's group, several other groups of German-speaking scientists developed various types of synthetic lubricating oils during the same time period, as documented in BIOS 1611, *Major Developments in Synthetic Lubricants and Additives in Germany*, pp. 92–93 and 99–100:

> In the investigation of the German oil industry and interrogation of the leading personnel, certain facts have come to light which show that Germany had a well-developed synthetic lubricating oil industry already in being, and undergoing rapid expansion. Although from a quantity basis the products obtained from natural petroleum resources predominated, it would appear that from the quality standpoint the synthetic production was of most importance. [...]
>
> As would be expected, the outstanding developments were made under the auspices of the I.G. Farbenindustrie. It would appear that as early as 1927 a department under Dr. Zorn at Ludwigshafen commenced research on the polymerisation of olefines for the production of lubricants, this work being coupled with an investigation of the possible constituents of lubricating oils by synthesis of likely hydrocarbons; this work was similar to but apparently much wider in scope than that of Mikeska.
>
> By 1936 the process based on the polymerisation of ethylene was developed and production started in 1937 at Leuna, and later at Schkopau. By Government order this development was kept secret. Similar processes but based on the production of olefines by wax cracking were developed and operated by the I.G. and Vakuum at Pölitz and Rhenania Ossag (Shell) at Harburg. [...]
>
> Besides the above developments, Ruhrchemie produced about 1500 tons/month of a synthetic automotive engine oil (based on Fischer-Tropsch products) of a rather unsaturated, easily oxidisable character, which was used by the Army[...] [...] Rheinpreussen A.G., Homberg produced spindle oil, machine oil and steam cylinder oil, each of which found application in the various Services, particularly the Navy, where the aromatic character of the products was found beneficial in diesel engine lubricants. Other low pour steam cylinder oils were produced at Pölitz and Ludwigshafen, the latter by the Paraflow synthesis. [...]
>
> Reviewing the above topics as a whole it is apparent that in the synthetic field particularly, the Germans were ahead of the Allied developments, especially in their widespread application of the adipic ester type of lubricant. [...] Certainly some of the uses already explored experimentally open up very interesting fields for development, particularly in the lubrication of internal combustion engines.

The synthetic lubricating oils and additives that were invented by Zorn and other German-speaking scientists were extensively studied by Allied countries [e.g., BIOS 373; BIOS 1611; CIOS XXXII-68; CIOS XXXII-94; CIOS XXXII-107.] Now they are widely used around the world.

PRODUCTION OF HIGH QUALITY LUBRICATING OILS

Wilhelm Pungs, Ludwigshafen - on - the - Rhine, Hans Rabe, Mannheim, and Hermann Zorn, Ludwigshafen - on - the - Rhine, Germany, assignors to I. G. Farbenindustrie Aktiengesellschaft, Frankfort-on-the-Main, Germany

Application January 30, 1931, Serial No. 512,488, and in Germany February 3, 1930

5 Claims. (Cl. 196—78)

The present invention relates to the production of high quality lubricating oils, in particular from paraffin waxes.

It is already known that viscous oils are obtained when olefinic hydrocarbons either alone or in admixture with other hydrocarbons are subjected to the action of catalysts, as for example those of the Friedal craft synthesis such as aluminium chloride and the like. The olefinic hydrocarbons employed for this process may be obtained for example by cracking.

We have now found, contrary to expectation, that when employing products obtained by cracking from paraffinic hydrocarbons, in particular hydrocarbon mixtures comprising paraffin wax, such as petroleum or hard or soft paraffin waxes, the nature of the cracking is of extreme importance for the yields and quality of the lubricating oils to be obtained. For example if the cracking is carried out so that the resulting liquid products are strongly unsaturated and have an iodine value which is above 150, preferably above 200, the subsequent condensation (under which term we understand also the polymerization) in the presence of catalysts having a condensing action, as for example anhydrous halides giving rise to a strong evolution of heat when treated with water, such as aluminium chloride, iron chloride, zinc chloride, boron fluoride or catalysts having a similar action, yield particularly high quality lubricating oils. The iodine value which, as is known, is the number of parts of halogen, reckoned as iodine, which combine with 100 parts of the oil to be investigated, is determined by treating said oil while dissolved in carbon tetrachloride and in the dark with a fixed amount of a ⅕ normal aqueous solution of potassium bromate containing 40 grams of potassium bromide per litre and an excess of a 10 per cent hydrochloric acid solution and determining in the known manner the amount of bromine not combined with the oil. The most favourable temperature for a cracking of this kind in which almost all the paraffinic constituents of the initial material to be treated are decomposed with the formation of unsaturated hydrocarbons depends on the nature of the initial material and also on the catalyst added and the apparatus used and must be ascertained in each case by a preliminary experiment. In all cases where cracking temperatures below 600° C. are employed, the process is carried out for example in the presence of dehydrogenating catalysts such as turnings of copper, V2A-steel, masses obtained by sintering a mixture of the powders of copper, iron and nickel, and the initial materials are treated until the content of unsaturated hydrocarbons is as high as possible and the said iodine value has been surpassed.

This iodine value is surpassed for example by cracking a soft paraffin wax melting at from 40° to 42° C. under ordinary pressure and at a temperature of 540° C. For the same purpose a hard paraffin wax obtained from brown coal tar and melting between 51° and 53° C. is preferably first cracked under a pressure of from 4 to 6 atmospheres and then in a second cracking stage under ordinary pressure and at a temperature of about from 515° to 520° C. An American unwashed wax is cracked under ordinary pressure at about 525° C. Petrolatum is cracked under ordinary pressure at 540° C., the non-converted portion being cracked at 6 atmospheres and the pressure-cracked products being subjected to a temperature of 530° C. With other paraffinic hydrocarbon materials it may easily be determined by preliminary experiment, which order of sequence of the single cracking stages provided several steps are employed, what temperature and velocity of flow are most suitable for obtaining a product having an iodine value of more than 150.

When working under ordinary pressure it is preferable for the sake of economy to reduce the formation of gas to a minium. The formation of gas is dependent on the temperature and on the velocity of the treated materials. With the same velocity of flow the losses by formation of gas are greater at higher temperatures than at lower temperatures, whereas with the same temperatures these losses are greater at lower velocities of flow than at higher velocities of flow, so that at higher temperatures greater velocities of flow may be employed. On account of the high cracking temperatures the cracking operation is carried out in the vapor phase if ordinary pressures are employed.

Particularly good results are obtained by cracking the initial paraffinic hydrocarbons first under an elevated pressure, which may range to about 10 atmospheres, and at a moderately elevated temperature, and then subjecting the products thus obtained to further cracking under ordinary pressure and at higher temperatures. The sequence of these stages may also be changed, if desired. When working in several stages in the manner described the loss by evolution of gas is less than when cracking only in one stage and under ordinary pressure. On the other hand, if the cracking were carried out only at elevated

1,965,952

PRODUCTION OF HIGH QUALITY LUBRICATING OILS

Hermann Zorn and Martin Mueller-Cunradi, Ludwigshafen-on-the-Rhine, and Walter Rosinsky, Oppau, Germany, assignors to I. G. Farbenindustrie Aktiengesellschaft, Frankfort-on-the-Main, Germany

Application February 28, 1931, Serial No. 519,250 In Germany March 25, 1930

10 Claims. (Cl. 196—78)

The present invention relates to the production of high quality lubricating oils.

We have found that high quality lubricating oils are obtained by condensing, in the presence of condensing agents, and, if desired, while supplying heat and adding gaseous olefines, two different liquid hydrocarbons, one being liquid higher aliphatic olefines, such as aliphatic olefines containing more than five carbon atoms in the molecule or mixtures essentially comprising the same, and the second being liquid hydrocarbons capable of undergoing condensation or polymerization reactions under the influence of aluminum chloride, that is, unsaturated hydrocarbons different from said liquid olefines, or cyclic hydrocarbons. Mixtures containing said unsaturated or cyclic hydrocarbons as essential constituents with some paraffinic hydrocarbons can also be advantageously employed.

The said liquid olefines may be obtained by cracking higher paraffinic hydrocarbons, i. e., paraffinic hydrocarbons containing more than five carbon atoms in the molecule as, for example, by cracking solid paraffins or paraffinic oils at temperatures ranging from about 450 to 500° C. or more, under elevated pressures and, if desired, with the addition of methane, or by dehydrating aliphatic alcohols or by other known methods.

The said other condensable hydrocarbons may, on the other hand, be supplied by the use of tars, mineral oils or their liquid distillation, extraction or cracking products of a nature different from said liquid olefines or the destructively hydrogenated products of coals, tars, mineral oils and the like. Hereinafter and in the claims coals, tars, mineral oils and the like are referred to as bituminous materials.

In carrying out the condensation, it is preferable not to mix the single initial materials before the addition of the condensing agent, but first to bring together one of the components with the condensing agent and to effect a partial condensation preferably at the temperature most favorable for the purpose, the other component then being added, and the treatment completed, if desired at a temperature most favorable for the condensation then proceeding. The most favorable temperature in each case may be readily ascertained by a preliminary experiment on a small scale. The temperature employed will usually be below 150° C. For example, starting with the condensation of liquid olefines, the amount of heat set free is usually sufficient to produce the most favorable reaction temperature. When the other components are then added, as for example a brown coal tar oil freed from phenol, it is preferable to supply heat since the further condensation usually necessitates a higher temperature than the first phase. However, when starting with tar oil and adding the condensing agent it is preferable to supply heat in order to attain the most favorable reaction temperature; when liquid olefines are added after the condensation, the external supply of heat is usually no longer necessary for the further course of the condensation process. Temperatures of up to 200° C. or sometimes higher have proved advantageous in practice.

According to the present invention, gaseous olefines, as, for example ethylene, propylene, butylene, such as are formed for example by the cracking of hydrocarbons may be employed conjointly, for example they may be led in during the condensation process.

Further, the process may be carried out by exposing each of the components to the action of the condensing agent singly, the resulting products including the condensing agents then being combined and further treated at a suitable temperature.

The process according to the present invention may be carried out at atmospheric or increased pressure. Anhydrous halides, which give rise to a considerable evolution of heat when mixed with water, such as aluminium chloride, ferric chloride, zinc chloride, tin tetrachloride, boron fluoride, anhydrous hydrofluoric acid and the like or complex acids, as for example zinc chloride-acetic acid, or boric acid-oxalic acid, are suitable as condensing agents. Bleaching earths, such as a naturally occurring bleaching earth of large surface, essentially consisting of aluminum hydrosilicate activated with aqueous hydrochloric acid may also be employed.

In some cases it may be preferable to carry out the single stages of the treatment with different condensing agents as for example first to treat the liquid olefines with boron fluoride and then, after the addition of the other component, further to condense with aluminium chloride, or

PRODUCTION OF LUBRICATING OILS

Hermann Zorn and Gerhardt Hofmann, Ludwigshafen-on-the-Rhine, and Walter Rosinsky, Oppau, Germany, assignors to I. G. Farbenindustrie Aktiengesellschaft, Frankfort-on-the-Main, Germany

No Drawing. Application November 25, 1932, Serial No. 644,324. In Germany December 3, 1931

10 Claims. (Cl. 87—9)

The present invention relates to improvements in the production of lubricating oils.

It has already been proposed to use fatty oils as such for lubricating purposes or to employ them in admixture with mineral lubricating oils. The fatty oils are, however, but little suited for continuous operation.

We have found that valuable lubricating oils having the character of mineral lubricating oils are obtained from vegetal, i. e. vegetable or animal, fatty substances, such as fats or fatty oils, by converting them into unsaturated products which are practically free from oxygen, i. e. which preferably contain not more than about 1 per cent of oxygen, and which contain either the same number of carbon atoms in the molecule as, or a smaller number thereof than, the initial materials, and then subjecting these products to condensation in the presence of condensing agents. The term "condensation" is to include also the polymerization for the purposes of the present invention. The said condensation may also be effected together with other reactive substances, as for example hydrocarbons containing double carbon linkages in the molecule, such as aromatic hydrocarbons, liquid or gaseous olefines, mineral or tar oils or their conversion products. The said conversion of vegetal fatty substances into unsaturated products practically free from oxygen is effected at temperatures ranging between 300° and 500° C., preferably between 420° and 480° C. and preferably in the presence of catalysts having a splitting action, as for example copper, copper chromite and other compounds of copper, if desired together with other substances. Hydrogen may also be present in this treatment. This direct conversion into unsaturated hydrocarbons is usually effected under ordinary pressure, but also elevated pressures ranging up to 50 atmospheres may be employed. The unsaturated conversion products may also be prepared by heating the initial materials to temperatures between 200° and 300° C., preferably between 200° and 250° C., in the presence of hydrogen, at pressures ranging between 50 and 300 atmospheres and while employing catalysts having a reducing action, as for example copper chromite, copper, mixtures of copper oxide and aluminium oxide, whereby the said materials are converted into the alcohols corresponding to the fatty acids present, the alcohols then being dehydrated in the usual manner.

As the initial materials may be mentioned for example vegetable or animal fats or fatty oils, such as soya bean oil, olive oil, palm oil, bone oil and the like. In order to prepare for example from soya bean oil the unsaturated conversion products which are practically free from oxygen, the procedure may be as follows:—

The initial material, if desired with an addition of hydrogen and preferably in the presence of one of the aforesaid catalysts having a splitting action, as for example a mixture of the oxides of copper and aluminium, is heated to temperatures of from about 300° to 500° C. or more, increased pressure being employed if desired.

The unsaturated hydrocarbon mixture obtained from the vegetal fatty substances, if desired after removing any small amount of cleavage products containing oxygen, as for example acrolein, free fatty acids and the like, and preferably after the addition of the beforementioned reactive products, as for example mineral oil, is condensed with the usual condensing agents, in particular anhydrous halides of the Friedel-Crafts type, such as aluminium chloride, zinc chloride, tin tetrachloride, boron fluoride and the like, at a temperature ranging between 0° and 200° C., preferably between 40° and 100° C., to form valuable viscous oils.

The products obtained are viscous lubricating oils which are distinguished by a flat temperature-viscosity curve. They may be added to other lubricating oils in order to improve them.

The following examples will further illustrate the nature of this invention, but the invention is not restricted to these examples. The parts are by weight.

Example 1

100 parts of soya bean oil are led over a catalyst of copper and aluminium at 425° C. 80 parts of a product are obtained free from oxygen and boiling between 60° and 360° C. This is stirred for 2 hours at 120° C. with an addition of 6 parts of aluminium chloride. After decanting from the sludge of aluminium chloride, a crude lubricating oil is obtained which when distilled up to a temperature of 160° C. at 1 millimetre (mercury gauge) yields 20 parts of an oil as first runnings

5 Claims. (Cl. 196—78)

The present invention relates to the production of high quality lubricating oils.

We have found that very valuable and high quality lubricating oils are obtained by adding to hydrocarbon oils, as for example mineral and tar oils, destructive hydrogenation products of coals, cracking and destructive hydrogenation products of mineral and tar oils and of fatty oils and their extraction and distillation products, polymerized isobutylene, advantageously highly polymerized isobutylene, the resulting solutions being subjected to a treatment with condensing or polymerizing agents. The peculiar property of the polymerized isobutylene, especially of the highly polymeric product, of being capable of flattening the temperature-viscosity curve is considerably increased by the said treatment with condensing agents. For example an isobutylene polymerization product of high molecular weight when dissolved in an amount of 1 per cent in lubricating oil having a viscosity index of 55, imparts to the lubricating oil a viscosity index of 90 and a viscosity of 2.4° Engler at 99° C. If this solution be treated with aluminium chloride, an oil having a viscosity index of 100 and a viscosity of 2.2° Engler at 99° C. is obtained. Thus an improvement in the temperature-viscosity curve of the oil takes place without the viscosity of the oil being increased at the same time. This would take place, however, if the improvement in the viscosity index were effected by the addition of further amounts of the highly polymerized additional substance. Up to 30 per cent and more of the polymerized isobutylene may be added to the oils to be improved, depending on the desired effect and the nature of the oil, but amounts of from 0.1 to 10, preferably from 0.5 to 2 per cent are usually sufficient.

The anhydrous halides of the Friedel-Crafts type, such as the anhydrous chlorides of aluminium, zinc, tin and iron are suitable, for example, as condensing or polymerizing agents. They are usually employed in amounts of from 0.5 to 10, preferably from 1 to 3, per cent, with reference to the oil mixture to be reacted upon. Their action is promoted by vigorous stirring to effect a thorough mixing and by the employment of increased temperatures. The viscosity index and the viscosity of the products resulting from the treatment are dependent on a temperature optimum which may be readily ascertained for each initial material by a simple preliminary experiment. In most cases the most favorable temperatures are between 40° and 80° C., but also higher or lower temperatures, for example between 10° and 110° C., may be satisfactorily employed.

Mineral oils, tar oils, oils derived from the destructive hydrogenation of coals, their distillation, extraction, cracking and destructive hydrogenation products and fractions containing low to high boiling unsaturated hydrocarbons, such as benzines, middle oils, gas oils and lubricating oils, are suitable as initial materials. Cracking products of fatty oils and their dehydrated destructive hydrogenation products are also suitable. Mixtures of the said initial materials may also be employed.

The reaction may be carried out in a great variety of ways. For example the additional substance of high molecular weight may be dissolved in a lubricating oil to be improved, the condensing or polymerizing agent added, the whole warmed and stirred for some time and the condensing or polymerizing agent separated either by sedimentation and decanting or by washing out with water. A part of the initial material, as for example a half, may also be partially polymerized or condensed alone, then mixed with the other half containing the additional substance of high molecular weight in solution and the polymerization or condensation process being completed. This method of working is especially suitable when employing or co-employing cracking products, in particular those of hard or soft paraffin wax or of petrolatum or crude paraffin wax. The condensing agent, as for example aluminium chloride, may then be added to the cracking product, as for example of paraffin wax, and the whole stirred for some time, as for example an hour. Heating spontaneously occurs because the reaction proceeds exothermically. The lubricating oil fraction of a mineral or tar oil is then added in which the high molecular additional substance has previously been dissolved, and stirring is continued for some time while heating. When employing aluminium chloride as the condensing agent, lubricating oil fractions which have not been purified and which still contain asphaltic substances may be employed, the known purifying action of aluminium chloride being thus utilized at the same time. The asphaltic impurities of the original oil are contained in the aluminium chloride sludge which separates at the end of the reaction and may be removed from the oil by decantation.

The accompanying drawing represents diagrammatically one form of apparatus which is

Figure 3.199: Hermann Zorn led a group at I.G. Farben Ludwigshafen that invented and mass-produced synthetic lubricating oils and additives during the period 1927–1945.

3.9.4 Synthetic Detergents and Paper Recycling

Traditional soap-making requires animal fat. Even during peacetime and certainly during wartime, most animal fat in the German-speaking world was needed for cooking purposes. Therefore it was in short supply for soap, and there was a strong incentive to find synthetic chemical alternatives. German-speaking chemists developed both inorganic and organic detergents using methods of direct chemical synthesis.[20] Such synthetic detergents are now used worldwide, since they proved to have superior properties and lower production costs compared to traditional soaps.

In 1876, Friedrich (Fritz) Henkel (German, 1848–1930) founded the Henkel & Cie. soap company and began producing the first synthetic inorganic detergent powder, a mixture of sodium carbonate for bleaching and sodium silicate for abrasive cleaning. See Fig. 3.200. Later Henkel's sons joined the company; in particular, his third son, Hugo Henkel (German, 1881–1952), obtained a Ph.D. in chemistry and became the head chemist for the Henkel company. In 1907, Hugo Henkel invented and began selling an improved inorganic detergent powder, using sodium perborate for bleaching and sodium silicate for abrasive cleaning, that was dubbed Persil for those two components. Hugo Henkel and Otto Gessler (German, 18??–19??) also invented the first successful methods of recycling printed paper by using similar bleaching and cleaning compounds. Along the way, the Henkels and several other chemists in their company developed a variety of other chemical products, including new adhesives (and later the first glue stick, Pritt).

In contrast to inorganic detergents, organic detergents such as those made from animal fat contain long hydrocarbon molecules that are better able to interact with and remove hydrocarbon stains such as grease. Thus there was a strong need to develop synthetic organic detergents.

Perhaps the most important chemist in the development of synthetic organic detergents was Fritz Günther (German, 1877–1957), who led a large research group devoted to that topic at BASF in Ludwigshafen (which became I.G. Farben Ludwigshafen). Günther and his group began working on the problem during World War I and produced their first commercial synthetic organic detergent, called Nekal, in 1916.

Günther and his group developed a wide range of other synthetic organic detergents over the following decades: Nekalin, alkylbenzene sulfonates (ABS) such as sodium dodecyl benzene sulfonate, and others. See Fig. 3.201. Günther retired in 1938 due to failing eyesight (possibly caused by prolonged chemical exposure), yet his group at Ludwigshafen remained highly active until at least 1945.

At I.G. Farben Höchst, Hermann Ludwig Orthner (German, 1897–1971) ran another important group that developed and mass-produced synthetic organic detergents such as Igepon/Hostapon and Mersol until at least 1945 (Fig. 3.202). For example, BIOS 1222, *Mersol and Hostapon Processes, I.G. Farbenindustrie, Höchst*, p. 1, reported:

---

[20] Baird 1955; Gritz 2013, 2014; BIOS 518; BIOS 1222; FIAT 913.

> During the war the I.G. Farbenindustrie manufactured large quantities of Mersol type products from a hydrogenated Fischer Tropsch cut, Mepasin. Large scale manufacture of this product was carried out at Leuna and Wolfen, but the development work was done at Höchst under Professor Orthner. Höchst laboratories also developed two further processes for detergents (Hostapon) of the same type from Mepasin.

German-speaking scientists also invented methods of mass-producing and purifying enzymes (such as proteases that degrade proteins and lipases that degrade fats) and adding them to commercial detergents to improve their cleaning power (see for example p. 2353).

Many of these German developments were patented and known through those patents to other countries from the early 1900s onward. Others were not adopted by other countries until Allied investigators interrogated German scientists and visited plants after World War II. Synthetic detergents and detergents incorporating cleaning enzymes are now commonly used worldwide. Recycling of printed paper, as first developed by Hugo Henkel and Otto Gessler, is also used worldwide.

Persil synthetic detergents and paper recycling

HAUPTPATENT

HENKEL & Cie., Düsseldorf (Deutschland).

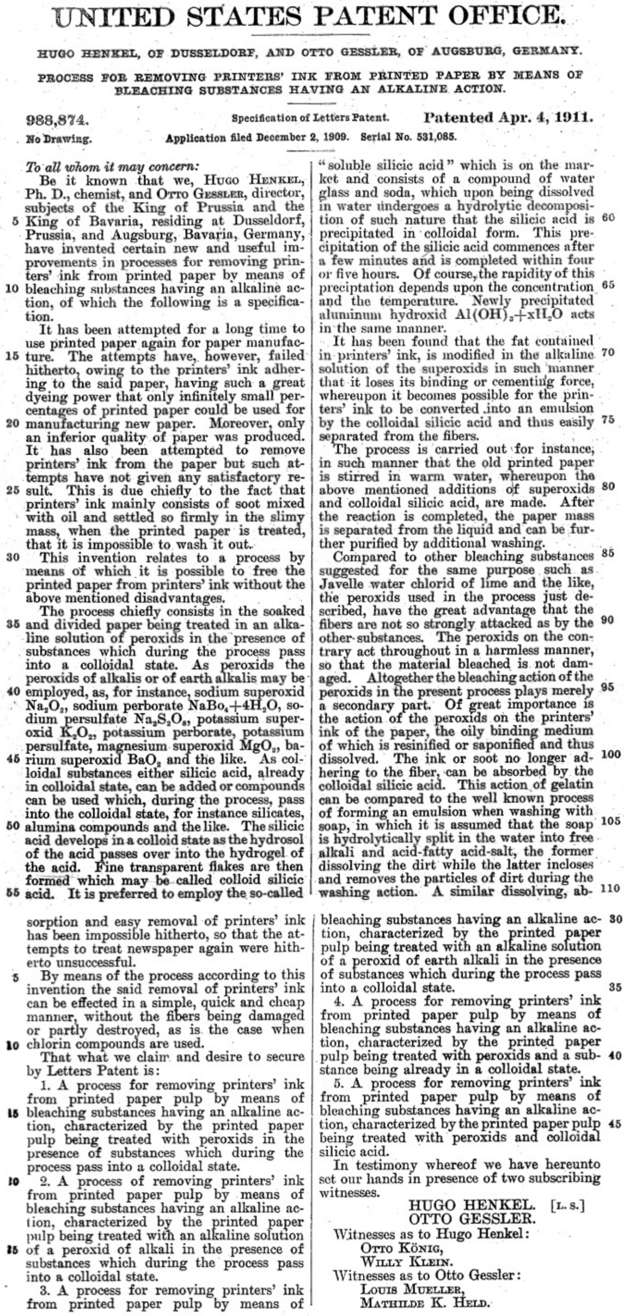
Verfahren zur Überführung von Alkalisilikatlösungen in trockene, leicht lösliche Pulver.

Es besteht schon seit langem in der Industrie das Bedürfnis nach einem pulverförmigen, leicht löslichen Alkalisilikat, da ein solches handlicher ist als die üblichen Lösungen, deren Verwendung für manche Zwecke, so z. B. für pulverförmige Farben und dergleichen, überhaupt ausgeschlossen ist. Die bisher vorgeschlagenen Wege zur Überführung z. B. von Wasserglas haben aber nur ein in kochendem oder heißem Wasser lösliches Produkt ergeben.

Die vorliegende Erfindung betrifft nun ein Verfahren zur Überführung von Alkalisilikatlösungen in trockene, leicht lösliche Pulver. Das Verfahren beruht darauf, daß man unter hohem Druck stehende, bei hoher Temperatur konzentrierte, heiße, zähflüssige Alkalisilikatlösungen durch plötzliche Druckentlastung in Form eines feinen Staubes mit kalter Luft in Berührung bringt.

Beispiel:

Man löst zunächst in einem rotierenden Wasserglas-Autoklaven, der unter hohem Druck, etwa 6—8 Atmosphären, steht, die übliche Ausgangssubstanz für die Herstellung von Wasserglaslösungen in Wasser auf. Das Auflösen wird bei höherer Temperatur vorgenommen, bis die dickflüssige Lösung ein spezifisches Gewicht von 1,44 besitzt. Die so erhaltene Lösung ist in heißem Zustand zähflüssig und nimmt beim Erkalten die Form einer zähen, unbeweglichen Gallerte an. Die heiße Lösung wird nun unter hohem Druck von 8 Atmosphären, der beständig aufrecht erhalten wird, durch eine Streudüse mit Öffnungen von etwa anderthalb Millimeter Durchmesser aus dem Autoklaven austreten gelassen. Die staubförmige Lösung wird unter der Einwirkung kalter Luft sofort in eine feste, trockene Form übergeführt. Diesen Vorgang unterstützt man dadurch, daß man mit einem kalte Luft zuführenden Ventilator das staubförmige Material durch einen Holzschacht etwa 4 Meter hoch in die Höhe führt, um es dann allmählich als vollkommen trockenes Pulver auf den Boden sinken zu lassen. Das auf den Boden sinkende, staubförmige Material enthält 10 bis 15 % weniger Wasser als die heiße Lösung. Durch die in der Luft enthaltene Kohlensäure wird die Oberfläche der Wasserglasstäubchen mit einer feinen Haut umgeben, wie dies stets



UNITED STATES PATENT OFFICE.

HUGO HENKEL, OF DUSSELDORF, AND OTTO GESSLER, OF AUGSBURG, GERMANY.

PROCESS FOR REMOVING PRINTERS' INK FROM PRINTED PAPER BY MEANS OF BLEACHING SUBSTANCES HAVING AN ALKALINE ACTION.

988,874. Specification of Letters Patent. **Patented Apr. 4, 1911.**

No Drawing. **Application filed December 2, 1909. Serial No. 531,085.**

To all whom it may concern:

Be it known that we, Hugo Henkel, Ph. D., chemist, and Otto Gessler, director, subjects of the King of Prussia and the King of Bavaria, residing at Dusseldorf, Prussia, and Augsburg, Bavaria, Germany, have invented certain new and useful improvements in processes for removing printers' ink from printed paper by means of bleaching substances having an alkaline action, of which the following is a specification.

It has been attempted for a long time to use printed paper again for paper manufacture. The attempts have, however, failed hitherto, owing to the printers' ink adhering to the said paper, having such a great dyeing power that only infinitely small percentages of printed paper could be used for manufacturing new paper. Moreover, only an inferior quality of paper was produced. It has also been attempted to remove printers' ink from the paper but such attempts have not given any satisfactory result. This is due chiefly to the fact that printers' ink mainly consists of soot mixed with oil and settled so firmly in the slimy mass, when the printed paper is treated, that it is impossible to wash it out.

This invention relates to a process by means of which it is possible to free the printed paper from printers' ink without the above mentioned disadvantages.

The process chiefly consists in the soaked and divided paper being treated in an alkaline solution of peroxids in the presence of substances which during the process pass into a colloidal state. As peroxids the peroxids of alkalis or of earth alkalis may be employed, as, for instance, sodium superoxid Na_2O_2, sodium perborate $NaBo_4+4H_2O$, sodium persulfate $Na_2S_2O_8$, potassium superoxid K_2O_2, potassium perborate, potassium persulfate, magnesium superoxid MgO_2, barium superoxid BaO_2 and the like. As colloidal substances either silicic acid, already in colloidal state, can be added or compounds can be used which, during the process, pass into the colloidal state, for instance silicates, alumina compounds and the like. The silicic acid develops in a colloid state as the hydrosol of the acid passes over into the hydrogel of the acid. Fine transparent flakes are then formed which may be called colloid silicic acid. It is preferred to employ the so-called "soluble silicic acid" which is on the market and consists of a compound of water glass and soda, which upon being dissolved in water undergoes a hydrolytic decomposition of such nature that the silicic acid is precipitated in colloidal form. This precipitation of the silicic acid commences after a few minutes and is completed within four or five hours. Of course, the rapidity of this preciptation depends upon the concentration and the temperature. Newly precipitated aluminum hydroxid $Al(OH)_3+xH_2O$ acts in the same manner.

It has been found that the fat contained in printers' ink, is modified in the alkaline solution of the superoxids in such manner that it loses its binding or cementing force, whereupon it becomes possible for the printers' ink to be converted into an emulsion by the colloidal silicic acid and thus easily separated from the fibers.

The process is carried out for instance, in such manner that the old printed paper is stirred in warm water, whereupon the above mentioned additions of superoxids and colloidal silicic acid, are made. After the reaction is completed, the paper mass is separated from the liquid and can be further purified by additional washing.

Compared to other bleaching substances suggested for the same purpose such as Javelle water chlorid of lime and the like, the peroxids used in the process just described, have the great advantage that the fibers are not so strongly attacked as by the other substances. The peroxids on the contrary act throughout in a harmless manner, so that the material bleached is not damaged. Altogether the bleaching action of the peroxids in the present process plays merely a secondary part. Of great importance is the action of the peroxids on the printers' ink of the paper, the oily binding medium of which is resinified or saponified and thus dissolved. The ink or soot no longer adhering to the fiber, can be absorbed by the colloidal silicic acid. This action of gelatin can be compared to the well known process of forming an emulsion when washing with soap, in which it is assumed that the soap is hydrolytically split in the water into free alkali and acid-fatty acid-salt, the former dissolving the dirt while the latter incloses and removes the particles of dirt during the washing action. A similar dissolving, ab-

sorption and easy removal of printers' ink has been impossible hitherto, so that the attempts to treat newspaper again were hitherto unsuccessful.

By means of the process according to this invention the said removal of printers' ink can be effected in a simple, quick and cheap manner, without the fibers being damaged or partly destroyed, as is the case when chlorin compounds are used.

That what we claim and desire to secure by Letters Patent is:

1. A process for removing printers' ink from printed paper pulp by means of bleaching substances having an alkaline action, characterized by the printed paper pulp being treated with peroxids in the presence of substances which during the process pass into a colloidal state.

2. A process of removing printers' ink from printed paper pulp by means of bleaching substances having an alkaline action, characterized by the printed paper pulp being treated with an alkaline solution of a peroxid of alkali in the presence of substances which during the process pass into a colloidal state.

3. A process for removing printers' ink from printed paper pulp by means of bleaching substances having an alkaline action, characterized by the printed paper pulp being treated with an alkaline solution of a peroxid of earth alkali in the presence of substances which during the process pass into a colloidal state.

4. A process for removing printers' ink from printed paper pulp by means of bleaching substances having an alkaline action, characterized by the printed paper pulp being treated with peroxids and a substance being already in a colloidal state.

5. A process for removing printers' ink from printed paper pulp by means of bleaching substances having an alkaline action, characterized by the printed paper pulp being treated with peroxids and colloidal silicic acid.

In testimony whereof we have hereunto set our hands in presence of two subscribing witnesses.

UNITED STATES PATENT OFFICE

FRITZ GÜNTHER, CURT SCHUSTER, AND JOSEF HETZER, OF LUDWIGSHAFEN-ON-THE-RHINE, GERMANY, ASSIGNORS TO I. G. FARBENINDUSTRIE AKTIENGESELLSCHAFT, OF FRANKFURT-ON-THE-MAIN, GERMANY, A CORPORATION OF GERMANY

WETTING, CLEANING AND EMULSIFYING AGENTS

No Drawing. Original application filed May 17, 1926, Serial No. 109,806, and in Germany May 22, 1925. Divided and this application filed September 24, 1928. Serial No. 308,134.

The present application has been divided out from our copending application No. 109,806 filed May 17, 1926.

It is known that sulfonic acids of alkylated hydrocarbons possess a high wetting power. It has also been suggested to employ synthetic tans containing sulfonic acid groups as cleaning agents.

We have now found that aromatic sulfonic acids which are not suitable for use as tanning materials (which property is ascertained by the incapability of the sulfonic acids of precipitating glue from its aqueous solutions) and which are substituted in the nucleus by at least one halogen atom or nitro hydroxyl or amino group, all of which may be designated as "active substituents", or by several such substituents and which also contain, whether in the nucleus or in the substituent, or in both, one or several alkyl groups, possess a high wetting power and are valuable substitutes for soaps and the like. Further they are excellently suitable for emulsifying organic liquids in water and for dispersing dyestuffs or other solid materials. The said sulfonic acids may be employed in the state of free acids or as salts which are equivalents for the purposes of the present invention. They offer the great advantage of giving stable dispersions also in acid solution and in the presence of calcium or other salts forming insoluble precipitates with ordinary soaps.

As examples of suitable sulfonic acids of the aforesaid type, we mention di-ethyl-metanilic acid, di-butyl-aniline sulfonic acids, N-di-amyl-alpha-naphthylamine sulfonic acid, isopropyl-chlor-naphthalene sulfonic acid, iso-propyl-naphthol sulfonic acids and the like or salts of such acids.

The following examples will further illustrate how our invention may be carried out in practice, but the invention is not limited to these examples. The parts are by weight.

Example 1

100 parts of a 10 per cent aqueous paste of indanthrene blue RS are intimately mixed with an aqueous solution of 1 part of di-ethyl-metanilic acid sodium salt and dried. A readily wettable powder which is finely dispersed when mixed with water, is obtained. Other dyestuffs can be treated in a similar manner, whether with the said sulfonic acid or for example with the di-amyl-alpha-naphthylamine sulfonic acid sodium salt.

Example 2

200 parts of di-butyl-aniline sulfonic acid sodium salt are dissolved in 1000 parts of water. The solution is mixed with 400 parts of methyl cyclo-hexanone. A clear solution is obtained which can be strongly diluted with water without becoming dull by a separation of methyl cyclo-hexanone and which is very suitable for use as a cleaning or washing agent.

When employing less di-butyl-aniline sodium sulfonate, methyl cyclo-hexanone or another difficultly soluble organic liquid is emulsified in an excellent manner, but no clear solution is obtained.

We do not lay claim, in this application, to the benzyl-aniline or ethyl-benzyl-aniline sulfonic acids since they are not efficient for the purpose of the present invention.

What we claim is:

1. The process of preparing aqueous emulsions of organic liquids difficultly soluble in water characterized by an addition of di-amyl-alpha-naphthylamine sulfonic acid sodium salt.

2. The process of producing stable dispersions of materials in water which comprises treating the materials with an aromatic sulfonic acid which is incapable of precipitating glue from its aqueous solution, contains at least one alkyl group and at least one active substituent, selected from the group consisting of amino and hydroxyl groups, and has a higher wetting power than benzyl-aniline and ethyl-benzyl-aniline sulfonic acids.

3. The process of preparing aqueous emulsions of organic liquids difficultly soluble in water characterized by an addition of an aromatic sulfonic acid, which is incapable of precipitating glue from its aqueous solution, contains at least one alkyl group and at least one active substituent selected from the group consisting of amino and hydrcxyl groups and

UNITED STATES PATENT OFFICE

FRITZ GÜNTHER AND JOSEPH NÜSSLEIN, OF LUDWIGSHAFEN-ON-THE-RHINE, GERMANY, ASSIGNORS TO I. G. FARBENINDUSTRIE AKTIENGESELLSCHAFT, OF FRANKFORT-ON-THE-MAIN, GERMANY, A CORPORATION OF GERMANY

SOAP PREPARATION

No Drawing. Application filed May 29, 1926, Serial No. 112,675, and in Germany June 2, 1925.

It is known that soaps (which term is hereinafter used in a broad sense including soft soaps, grain soaps, resin soaps, sulfonated caster oil or the salts thereof such as Turkey red oil and the like) cannot be employed in acid baths or in baths containing calcium or mangnesium salts, as they are decomposed with the separation of free fatty acids or with the formation of insoluble salts. Also, soap cannot be employed in salt water, for example sea-water.

We have now found that also in the above-mentioned acid baths and baths containing calcium or magnesium salts or salt water no separation of fatty acids or insoluble salts occurs and that accordingly the soaps are rendered useful therein, provided the soaps or the baths contain aromatic sulfonic acids possessing a high wetting power. As examples of such aromatic sulfonic acids we mention sulfonic acids of aromatic compounds containing hydrocarbon residues in their molecule, such as may be obtained for example by condensing aromatic sulfonic acids with aliphatic, hydroaromatic or aromatic-aliphatic alcohols, such as isopropyl alcohol, butyl alcohols, cyclo-hexanol, benzyl-alcohol and the like. The side chains may also link together two aromatic nuclei as is the case for instance in the condensation products of formaldehyde with naphthalene sulfonic acids. The said sulfonic acids may also contain other substituents such as halogen atoms or nitro or amino or hydroxyl groups and the side chain may also be attached to such substituents as for example in amyl-naphthylamine sulfonic acids and the like. The aromatic sulfonic acids may be employed in the state of free acids or of salts.

For example, soap may be employed in the process of dyeing in an acid bath by adding an aromatic sulfonic acid possessing a high wetting power, and very even dyeings are thereby obtained; it is possible to use even such dyestuffs which hitherto could only find restricted use on account of their small capability of producing even dyeings; further, the goods are penetrated with the color more thoroughly than without the said additions, the fastness to rubbing is increased and the time necessary for dyeing is diminished. Further, by our present invention wool fibre is protected from being damaged by alkalis as it can be washed and fulled in an acid bath, whereby often also a better result is obtained than with the methods heretofore employed.

The sulfonic acid of the character described or a salt thereof may be added to the bath containing a soap such as dyeing baths, carbonization baths, i. e. baths containing sulfuric acid in a strength of from 2 to 4° Baumé, fulling baths, washing or bleaching baths and the like, or mixtures of soaps with the sulfonic acids or their salts may be prepared beforehand. The said soaps may be neutral, alkaline or superfatted, and they may be employed in solution, or in the form of a paste or in the solid form. These preparations have the advantage of being easily stored or shipped and can be applied in a very simple manner. They possess the desirable properties of both the soaps and the sulfonic acids, and are especially stable against acid and hard or salt water. They produce a good lather with aqueous solutions containing acids or calcium or magnesium salts or similar obnoxious components such as produce precipitations with soaps, and thus counteract their effect and are capable of easily wetting. They can be employed for example for washing and cleaning purposes with water containing calcium or other salts or as an addition to dyeing baths containing acids or obnoxious salts. They are also very suitable for use with sea-water.

The said mixtures can be prepared in any desired manner, for example by heating a soap until it has entirely melted, and mixing the melt with the sulfonic acid or its salt or with a concentrated solution thereof or by kneading the soap with the dry salt and pressing the mixture to cakes or by mixing both in a powdery state or by adding the sulfonic acid during the saponification process. A mixture which is very suitable for most purposes consists for example of 80 parts of ordinary soap and 20 parts of a sulfonic acid of the character mentioned or a salt thereof. In case of water containing only small quan-

WETTING, CLEANSING, AND EMULSIFYING AGENT

Fritz Günther, Ludwigshafen-on-the-Rhine, Germany, assignor to I. G. Farbenindustrie Aktiengesellschaft, Frankfort-on-the-Main, Germany, a corporation of Germany

No Drawing. Application December 9, 1927, Serial No. 239,003. In Germany December 11, 1926

23 Claims. (Cl. 260—290)

The present invention relates to the manufacture and production of new wetting, cleansing and emulsifying agents.

I have found that products imparting to aqueous liquids excellent wetting, cleansing and emulsifying properties are obtained by mixing an organic acid wetting agent selected from the group consisting of sulfuric acid derivatives of high wetting power, that means true sulfonic acids of high wetting power, or sulfuric acid esters of the nature of Turkey-red oil, and naphthenic acids, with up to equivalent amounts of nitrogen-containing organic bases. Organic sulfonic acids of high wetting power which are to be employed according to the present invention comprise only such acids of which a 0.5 per cent aqueous solution of their sodium salt wets a felt-like textile fabric, for example, of wool or cotton in at the most one hour, but preferably in a much shorter time, for example in a few minutes. Organic sulfonic acids of the said kind which are particularly suitable for the purpose of the present invention are aromatic sulfonic acids containing alkyl-, aralkyl-, cycloalkyl-, or aryl groups, which may, if desired, be further substituted, whether in the nucleus or in the side chain, further sulfonic acids of aliphatic or hydroaromatic compounds, for example the sulfonation products of mineral oils, aliphatic tar oils, naphthenic acids and the like, as well as the known fat-splitting acids, or the ligno-sulfonic acids contained in sulfite-cellulose waste liquor. These acids yield excellent wetting, cleansing and emulsifying agents when treated with organic nitrogen-containing bases in the above specified amounts. As organic bases suitable for preparing the said agents, according to the present invention, aliphatic amines, such as methylamine or ethylamine, mono-, di-, or triethanolamine, but particularly the heterocyclic nitrogen-containing bases, such as pyridine and its homologues and derivatives, and the like, may be mentioned.

The said components for manufacturing the new products imparting to aqueous liquids a high wetting, cleansing and emulsifying action may be prepared before use by mixing them with each other in the absence of water in up to equivalent amounts, the nitrogenous base being always employed in a substantial quantity, i. e., in a quantity of at least 10 per cent of the equivalent amount, or by preparing them in the form of their salts by working in aqueous solution, or they may be produced only in the liquid or preparation with which they are to be used, by adding the required components thereto. It is to be understood that in the production of the new products no heating or other strong condition of working is applied, since otherwise condensation or other reactions would occur which may lead to the formation of water insoluble products.

When the substances are mixed no heat is applied and the usual reaction of an acid with a base occurs, namely, the formation of a salt corresponding for example to the following equations:

$R{-}O{-}SO_2{\cdot}OH$ + N ⟶ $R{-}O{-}SO_2$
Mono-sulfuric ester of compound R

$R{-}SO_2{\cdot}OH$ + N ⟶ $R{-}SO_2$
Sulfonic acid of compound R

$R{-}CO{\cdot}OH$ + N ⟶ $R{-}CO$
Carboxylic acid of compound R

The fact that a salt is actually formed is evidenced by the reduction of the acidity of the solutions of the acids when the nitrogenous base desired is added. These salts, moreover, are water-soluble salts since the formation of amides or imides would become obvious by the insolubility of the products.

It is not essential for the purpose of this invention that the equivalent quantity of the organic nitrogen bases is added to the acids. Even acids which are only partially so saturated exhibit an excellent wetting action. Very useful effects are also obtained with mixed salts prepared by adding to the said acids either several different organic nitrogen bases, or by replacing a portion of the latter by inorganic bases, such as caustic soda, ammonia and the like.

For preparing aqueous liquids of high wetting and cleansing properties it is generally sufficient to add to the liquids about 0.5 per cent of the said preparations. Aqueous liquids of a higher concentration, however, may also be used. If the said preparations are to be used for preparing highly stable aqueous emulsions or suspensions, or even clear aqueous solutions of sub-

FERDINAND MÜNZ AND KARL KELLER, OF FRANKFORT-ON-THE-MAIN-FECHENHEIM, AND FRITZ GÜNTHER, OF LUDWIGSHAFEN-ON-THE-RHINE, GERMANY, ASSIGNORS, BY MESNE ASSIGNMENTS, TO I. G. FARBENINDUSTRIE AKTIENGESELLSCHAFT, OF FRANKFORT-ON-THE-MAIN, GERMANY, A CORPORATION OF GERMANY

WETTING, CLEANSING, AND EMULSIFYING AGENTS AND PROCESS OF MAKING SAME

No Drawing. Application filed December 11, 1928, Serial No. 325,383, and in Germany December 15, 1927.

The present invention relates to wetting, cleansing and emulsifying agents and more particularly to mixtures of an alkylated naphthalene sulfonic acid compound with up to approximately equivalent amounts of an organic quaternary ammonium compound having the general formula:

$$X{-}\overset{Z}{\underset{R}{N}}{<}^{\text{alkyl}}_{\text{alkyl}}$$

wherein X means OH or an acid residue, Z represents an alkyl or an aralkyl group and R represents phenyl or naphthyl.

We have found that it is possible to obtain these products by mixing an organic sulfuric acid compound of the aforesaid kind with an organic quaternary ammonium compound, which may be done either by neutralizing the organic sulfuric acid derivative with the quaternary ammonium base or more simply by mixing an alkali salt of a wetting agent of the above mentioned kind with a salt of the quaternary ammonium base.

These new ammonium salts surpass the alkali salts of the wetting agents as to their wetting capacity even in an alkaline bath. The solubility of our new ammonium salts is already sufficient for their technical use, but it may be much increased by an addition of a protective colloid, of soaps of Turkey red oils or in a very simple manner by using an excess of the wetting agent applied, for instance about 9 parts of the wetting agent to one part of ammonium base.

In order to further illustrate our invention the following examples are given, the parts being by weight and all temperatures in centigrade degrees, but it may be understood that our invention is not limited to the particular products or reacting conditions mentioned therein.

Example 1

100 parts of the sodium salt of a dibutyl-naphthalene-sulfonic acid are mixed with 20 parts of dimethyl-phenyl-benzyl-ammonium-chloride. The mixture thus obtained is a dry, nearly colorless powder soluble in water to form a barely opalescent solution. It possesses a substantially higher wetting power than the wetting agent applied alone, in a neutral medium as well as in an acidic or an alkaline one. The probable course of the reaction may be illustrated as follows:

When using tetraethylammonium iodide as the quaternary ammonium salt, a product of similar properties is obtained.

Example 2

100 parts of free dibutyl-naphthalene sulfonic acid are introduced into a solution of 25 parts of the methyl-sulfuric acid salt of trimethyl-β-naphthyl-ammonium in about 250 parts of water. When the reaction is complete, the mass is allowed to settle. The bottom layer is a thick oil being the dibutyl-naphthalene sulfonic acid salt of trimethyl-β-naphthyl-ammonium. The oil may be used per se or mixed with a suitable Turkey red oil preparation in which case its solubility increases. The probable course of reaction may be illustrated as follows:

A similar product is obtained by starting from trimethyl-α-naphthyl-ammonium

Wasch- und Netzmittel

Patentiert im Deutschen Reiche vom 25. März 1933 ab
Patenterteilung bekanntgemacht am 12. September 1940

Es wurde gefunden, daß säureamidartige Kondensationsprodukte aus höhermolekularen Carbonsäuren und wasserlöslichen, durch Abbau von Eiweißstoffen erhaltenen Peptidgemischen sich besonders gut als Wasch- und Netzmittel eignen.

Es wurde schon vorgeschlagen, bei der Behandlung von Textilien u. dgl. Kondensationsprodukte von höhermolekularen Carbonsäuren einerseits mit einfachen einheitlichen Aminocarbonsäuren vom Typ des Glykokolls, anderseits mit hochmolekularen Eiweißspaltprodukten vom Typ der Lysalbin- und Protalbinsäure zu verwenden. Diesen bekannten Produkten gegenüber zeichnen sich die vorliegenden neuen Hilfsmittel aus durch ihre überlegene Waschwirkung, beispielsweise in der alkalischen Wollwäsche, und ihr erhöhtes Netzvermögen, besonders bei höherer Temperatur; sie übertreffen außerdem die Kondensationsprodukte einfacher einheitlicher Aminocarbonsäuren weit hinsichtlich der Säurebeständigkeit und des Kalkseifendispergiervermögens.

Die neuen Hilfsmittel sind durch in an sich bekannter Weise erfolgende amidartige Verknüpfung von Resten höhermolekularer Carbonsäuren mit wasserlöslichen Peptidgemischen, wie sie bei der weitgehenden Hydrolyse von Eiweißstoffen aller Art, wie Leder-, Haut-, Horn- oder Haarabfällen, Streckfleisch oder Schlachthofabfällen, Wollabfällen u. dgl., entstehen, erhältlich. Als Carbonsäurekomponente enthalten sie solche Säuren, die einen organischen Rest mit mindestens acht Kohlenstoffatomen besitzen, z. B. Undecylen-, Laurin-, Palmitin-, Stearin-, Öl- und Ricinolsäure sowie die aus Kokosöl, Palmkernöl, Baumwollsaatöl, Leinöl, Sojaöl, Holzöl, Rüböl, Tran u. dgl. erhältlichen Fettsäuregemische, sowie Fettsäuregemische aus der Oxydation von Kohlenwasserstoffen, wie Paraffin, oder von Rückständen der Verarbeitung von Fetten, Ölen oder Fettsäuren derselben; ferner Härtungsprodukte der genannten ungesättigten Säuren oder ihrer Gemische sowie Naphthensäuren, Harzsäuren, wie diejenigen des Tallöls, des natürlichen oder hydrierten Kolophoniums, aromatische, cycloaliphatische und hydroaromatische Carbonsäuren, z. B. Naphthoe-, Oxynaphthoesäuren oder Tetrahydronaphthalincarbonsäure.

Die Produkte lassen sich als Wasch- und Netzmittel bei den verschiedenartigsten Ver-

Waschmittel

Patentiert im Deutschen Reiche vom 5. April 1936 ab
Patenterteilung bekanntgemacht am 16. Mai 1940

Man hat schon vorgeschlagen, wasserlösliche Derivate der Cellulose, z. B. lösliche Salze der Celluloseschwefelsäureester, zum Schlichten und als Dispergierungsmittel zu verwenden. Eine praktische Anwendung als Waschmittel haben die wasserlöslichen Cellulosederivate bisher nicht gefunden, weil sie den Anforderungen, denen bei diesem Verwendungszweck genügt werden muß, nicht entsprochen haben.

Es wurde nun gefunden, daß man gut wirksame Waschmittel erhält, wenn man härtebeständige, synthetische organische Waschmittel mit löslichen Salzen von solchen Sulfonierungsprodukten der Cellulose oder von Celluloseäthern vermischt, in denen die Cellulose infolge besonders schonender Durchführung der Sulfonierung praktisch nicht abgebaut ist. Diese Sulfonierungsprodukte, beispielsweise von Cellulose, Methylcellulose, Oxäthylcellulose oder Methyloxäthylcellulose, geben verhältnismäßig viscose Lösungen.

Die Cellulosesulfonierungsprodukte, die für die erfindungsgemäßen Waschmittelmischungen verwendet werden, sind z. B. durch Einwirkung von Pyridinsulfonsäure bzw. Gemischen aus Pyridin und Chlorsulfonsäure auf Cellulose oder Celluloseäther bei verhältnismäßig niedrigen Temperaturen erhältlich. Ein anderer Weg ist der, daß man die Cellulose in flüssiger schwefliger Säure verteilt und Oleum oder Chlorsulfonsäure oder gasförmiges Schwefeltrioxyd zuführt. Im Schrifttum finden sich Angaben über die Herstellung dieser Stoffe, z. B. in Berichte der Deutschen Chemischen Gesellschaft, Jahrgang 61 (1928), S. 754 ff., und in der amerikanischen Patentschrift 2 025 073.

Waschmittel, denen die erfindungsgemäß anzuwendenden Cellulosesulfonierungsprodukte zuzusetzen sind, sind alle organischen Waschmittel, die gegen die Härtebildner des Wassers beständig sind, z. B. die Salze der sauren Schwefelsäureester von Fettalkoholen, Kondensationsprodukte aus Fettsäuren und Oxy- oder Aminoalkylsulfonsäuren oder Sulfonierungsprodukte von Verbindungen, die durch Einwirkung von Äthylenoxyd auf Hydroxyl-, Carboxyl- oder Aminogruppen enthaltende Stoffe entstehen.

Durch die Zugabe der Cellulosesulfonierungsprodukte zu den härtebeständigen Waschmitteln werden Produkte erhalten, die ein besseres Waschvermögen als die härtebeständigen Waschmittel allein besitzen.

6 **747 468**

den ist die Hydrierung beendet. Man filtriert vom Katalysator ab, destilliert Methanol ab, trocknet das zurückbleibende Amin und erhält 1200 Gewichtsteile eines Gemisches an tertiären Aminen. Bei der Destillation im Vakuum gehen zwischen 115 bis 165° bei 3 mm Druck 1150 Gewichtsteile eines farblosen Öles über, welches 5,03% titrierbaren Stickstoff und 4,98% tertiären Stickstoff enthält.

28 Gewichtsteile des so erhaltenen Amingemisches versetzt man mit 18 Gewichtsteilen Bromessigsäureäthylester und rührt bei 90 bis 100° etwa 4 Stunden lang. Das Reaktionsprodukt ist in kaltem Wasser klar löslich und stellt einen Betainester dar, der durch Natronlauge leicht verseifbar ist. Das Reaktionsprodukt kann entweder als solches oder nach der Verseifung gebraucht werden. Das Produkt kann aber auch dadurch hergestellt werden, daß man an Stelle von Bromessigsäureäthylester Chloressigsäureäthylester verwendet, dem man einige Prozent Bromessigsäureäthylester zusetzt.

Beispiel 13

Ein Netzmittel mit guten Beständigkeitseigenschaften erhält man nach folgender Vorschrift:

28 Gewichtsteile 10-Aminononadecan versetzt man mit 0,5 g Natriummethylat und leitet bei 150 bis 160° 13 Gewichtsteile Äthylenoxyd ein. Dann versetzt man das Reaktionsprodukt mit 14 Gewichtsteilen Dimethylsulfat und rührt bei erhöhter Temperatur, bis sich das Reaktionsprodukt klar in Wasser löst und auch beim Versetzen mit wenig verdünnter Natronlauge in Lösung bleibt. Das Reaktionsprodukt besitzt folgende Konstitution:

$$\begin{array}{c} \mathrm{C_9H_{18}\cdot CH\cdot C_9H_{18}} \\ | \\ \mathrm{CH_3\cdot N\cdot(CH_2-CH_2O)_3H} \\ \diagup\ \diagdown \\ \mathrm{CH_3 \quad OSO_3CH_3} \end{array}$$

Beispiel 14

Als gutes Netzmittel kann man ein Produkt, das man auf folgende Weise erhält, verwenden:

34 Gewichtsteile 8-Aminotricosan versetzt man bei 60 bis 70° unter Rühren mit 14 Gewichtsteilen Dimethylsulfat und rührt, bis sich eine Probe klar in Wasser löst und auch beim Versetzen mit wenig verdünnter Natronlauge klar bleibt.

Beispiel 15

Ein Netzmittel von großer Elektrolytunempfindlichkeit erhält man nach folgender Arbeitsweise:

6-Aminotricosan wird auf die gleiche Weise, wie im Beispiel 12 beschrieben, in 6-Dimethylaminotricosan übergeführt. 36 Gewichtsteile dieses Amins werden mit 2 Gewichtsteilen Bromessigsäureäthylester und 12 Gewichtsteilen Chloressigsäuremethylester versetzt und 5 Stunden unter Rühren auf 85 bis 90° am Rückflußkühler erhitzt. Nun wird mit der Lösung von 5,6 Gewichtsteilen Kaliumhydroxyd in 45 Gewichtsteilen Wasser verrührt und kurze Zeit bei 50 bis 60° gerührt. Das Reaktionsprodukt besitzt folgende Konstitution:

$$\begin{array}{c} \mathrm{C_5H_{11}\cdot CH\cdot C_{17}H_{35}} \\ |+ \\ \mathrm{CH_3\cdot N\cdot CH_2\cdot COO-} \\ | \\ \mathrm{CH_3} \end{array}$$

Beispiel 16

Als Heißnetzmittel eignet sich ein Produkt, das man wie folgt erhält:

Man führt 4-Aminoheptadecan in analoger Weise, wie es im Beispiel 4 beschrieben ist, in das Isocyanat über. Nun läßt man zu einer Lösung von 22 Gewichtsteilen Metanilsäure in 40 Gewichtsteilen Wasser, dem man die Lösung von 4 Gewichtsteilen Ätznatron in 10 Gewichtsteilen Wasser zugesetzt hat, unter gutem Rühren bei etwa 75° 28 Gewichtsteile des obigen Isocyanates tropfen und rührt etwa 10 Stunden bei der angegebenen Temperatur. Das Reaktionsprodukt ist klar in Wasser löslich. Es besitzt folgende Konstitution:

$$\begin{array}{c} \mathrm{C_3H_7\cdot CH\cdot C_{13}H_{27}} \\ | \\ \mathrm{NH} \\ | \\ \mathrm{C=O} \\ | \\ \mathrm{NHC_6H_4SO_3Na} \end{array}$$

Beispiel 17

Ein Netzmittel mit großer Beständigkeit gegen Alkalien wird auf folgende Weise erhalten:

28 Gewichtsteile 4-Aminoheptadecan versetzt man mit 19 Gewichtsteilen sulfoessigsaurem Natrium ($HO_2C\cdot CH_2\cdot SO_3Na$) und erhitzt auf 150 bis 160°, wobei man das auftretende Reaktionswasser azeotropisch mittels Xylol abdestilliert. Nach Beendigung der Wasserabspaltung und Entfernung des Xylols erhält man ein in heißem Wasser klar lösliches Produkt, das folgende Konstitution besitzt:

$$\begin{array}{c} \mathrm{C_3H_7\cdot CH\cdot C_{13}H_{27}} \\ | \\ \mathrm{NH} \\ | \\ \mathrm{O=C\cdot CH_2SO_3Na} \end{array}$$

Figure 3.202: Hermann Ludwig Orthner developed synthetic organic detergents from the 1930s to 1945.

3.9.5 Chemical Fabric Treatments

Scientists at I.G. Farben developed a wide variety of chemical treatments to make clothing and other fabrics resistant to fire, water, stains, wrinkling, etc. By the early 1940s, those chemical fabric treatments were in widespread production and use in the German-speaking world. Especially important in this area were Gustav Schwen's (German, 18??–19??) group of chemists at I.G. Farben Ludwigshafen and August Gutmann's (German, 18??–19??) group at I.G. Farben Höchst.

After the war, those chemical fabric treatments were closely inspected and eagerly adopted by Allied countries. Figures 3.203–3.205 show examples from one postwar Allied report, BIOS 518, *Textile Auxiliary Products of I.G. Farbenindustrie: Application, Testing and Miscellaneous Information.*

Another report, BIOS 698, *Survey of the German Heavy Textile Proofing Industry*, explained the great importance and innovation of the chemical treatments, for example for making fabrics simultaneously fire-retardant and water-resistant (especially useful for protective clothing for firefighters):

> FIREPROOFING
>
> Several of the firms visited had experience of this type of proofing mainly using the I.G. Akaustan products. The latter are mainly water soluble ammonium salts but Akaustan S is of particular interest in that it gives a water-insoluble fireproofing effect. It can be applied simultaneously with Persistol to give combined fireproofness and water repellency and there is reason to believe that this is probably the only known method of obtaining the combined proofing effects which does not interfere with the ventility of the cloth.

[See also FIAT 170.]

3.9.6 Firefighting Chemicals

In addition to creating fire-retardant fabrics, German-speaking scientists also made major improvements to chemical methods of fighting and extinguishing fires, and those were later adopted by Allied countries. For example, BIOS 704, *Mechanical Foam Liquid and Equipment*, reported:

> 6. Conclusions and Recommendations.
>
> (a) Substantial war time improvements were made in German foam fire fighting equipment.
>
> (b) Some German foam liquids are reported to be a blend of protein and synthetic materials. Protein foams were recognized as possessing the best fire extinguishing properties. Blending was necessary because of a shortage of protein materials.
>
> (c) The new standard German foam nozzle should be studied and tested.
>
> (d) The foam proportioner shown in Figure 2, has a very practical use in fire fighting. Development of a similar device for shipboard use is recommended.
>
> (e) Where adequate fire main pressure is not available to operate standard Navy foam fire fighting equipment, compressed air or carbon dioxide gas can be used to boost the pressure of water obtained from bilge pumps. Study and investigation of this principle for use on small Naval Craft is recommended.

PARTICULARS OF TARGET

22/1(g)/ Visits were made in September and October 1945 to the Höchst/(Frankfurt) and Ludwigshafen factories of the I.G.Farbenindustrie to obtain information on synthetic detergents and other textile auxiliary products manufactured at these works. The investigating team comprised:- 22/1(f)

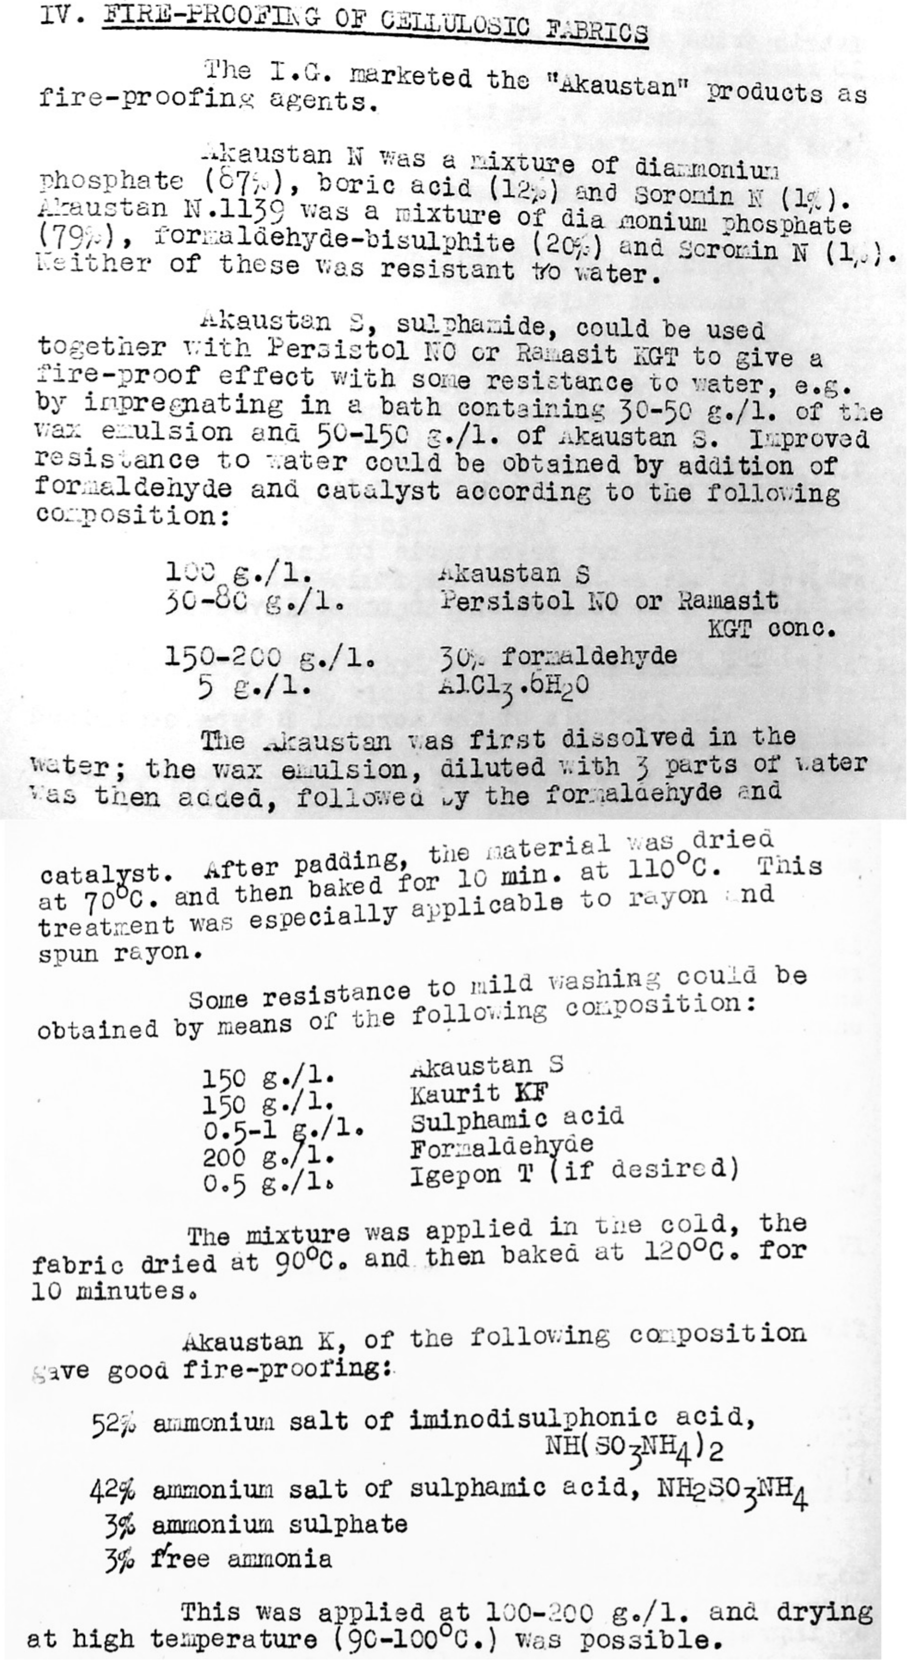
W.Baird	M. of S.
C.B.Brown	M. of S.
G.R.Perdue	M. of S.

The following personnel were interrogated on matters dealt with in this report:-

Dr Gutmann - Head of textile auxiliary application dept., Höchst
Dr Schwen - Head of textile auxiliary application dept., Ludwigshafen.
Dr Kuckertz - Head of section of Dr Schwen's dept., Ludwigshafen.
Dr Gurlt - Wool-dyeing laboratory, Höchst.
Dr Jackel - Wool-dyeing laboratory, Höchst.
Mr.Nestelberger Printing laboratory, Höchst.
Dr Greune - Head of central research laboratory, Höchst.
Dr Scheeffer - Fibre testing laboratory, Höchst.
Dr Ullrich - Head of textile auxiliary manufacture, Ludwigshafen.

The laboratories at Ludwigshafen had been badly damaged, but were under repair, while those at Höchst were undamaged.

Figure 3.204: Scientists at I.G. Farben developed a wide variety of chemical treatments to make fabrics resistant to fire, water, stains, wrinkles, etc. Those chemical fabric treatments were adopted by Allied countries [BIOS 518].



IV. FIRE-PROOFING OF CELLULOSIC FABRICS

The I.G. marketed the "Akaustan" products as fire-proofing agents.

Akaustan N was a mixture of diammonium phosphate (87%), boric acid (12%) and Soromin N (1%). Akaustan N.1139 was a mixture of diammonium phosphate (79%), formaldehyde-bisulphite (20%) and Soromin N (1%). Neither of these was resistant to water.

Akaustan S, sulphamide, could be used together with Persistol NO or Ramasit KGT to give a fire-proof effect with some resistance to water, e.g. by impregnating in a bath containing 30-50 g./l. of the wax emulsion and 50-150 g./l. of Akaustan S. Improved resistance to water could be obtained by addition of formaldehyde and catalyst according to the following composition:

100 g./l.	Akaustan S
30-80 g./l.	Persistol NO or Ramasit KGT conc.
150-200 g./l.	30% formaldehyde
5 g./l.	$AlCl_3.6H_2O$

The Akaustan was first dissolved in the water; the wax emulsion, diluted with 3 parts of water was then added, followed by the formaldehyde and catalyst. After padding, the material was dried at 70°C. and then baked for 10 min. at 110°C. This treatment was especially applicable to rayon and spun rayon.

Some resistance to mild washing could be obtained by means of the following composition:

150 g./l.	Akaustan S
150 g./l.	Kaurit KF
0.5-1 g./l.	Sulphamic acid
200 g./l.	Formaldehyde
0.5 g./l.	Igepon T (if desired)

The mixture was applied in the cold, the fabric dried at 90°C. and then baked at 120°C. for 10 minutes.

Akaustan K, of the following composition gave good fire-proofing:

52%	ammonium salt of iminodisulphonic acid, $NH(SO_3NH_4)_2$
42%	ammonium salt of sulphamic acid, $NH_2SO_3NH_4$
3%	ammonium sulphate
3%	free ammonia

This was applied at 100-200 g./l. and drying at high temperature (90-100°C.) was possible.

Figure 3.205: Scientists at I.G. Farben developed a wide variety of chemical treatments to make fabrics resistant to fire, water, stains, wrinkles, etc. Those chemical fabric treatments were adopted by Allied countries [BIOS 518].

3.9.7 “Superglue”

The family of isocyanate “superglue” products was developed in the 1930s by a large research group led by Otto Bayer (German, 1902–1982) at I.G. Farben Leverkusen. (The same group also developed polyurethane and other related products—see Fig. 3.160.)

BIOS 719, *Interview with Professor Otto Bayer, Formerly Member of the Directorate and Head of the Scientific Laboratories of the I.G. Farbenindustrie, Leverkusen*, provided information on that program:

> This interview was to obtain information on the chemistry of isocyanates and particularly the new polyisocyanates and their derivatives which have been intensively studied in Germany for some years.
>
> Professor Bayer confirmed that he had pioneered and developed this new isocyanate chemistry and stated that at Leverkusen he had had about 50–60 chemists and 200 other workers engaged on these problems.
>
> Professor Bayer was obviously an expert in his subject and had considerable knowledge of the synthesis, analysis, chemical properties, and industrial uses of the polyisocyanates and their derivatives. [...]
>
> Professor Bayer said that about 50 polyisocyanates have been prepared and examined in the laboratory. The more important of these are the following: [...]
>
> (c) Desmodur R. Triphenylmethane triisocyanate.
>
> This material was of importance for bonding rubber and Buna to various other surfaces, e.g. metals and textiles. [...]
>
> It is suggested by Professor Bayer that the adhesion obtained by the use of polyisocyanates in bonding rubber to metal is due to a film of oxide and moisture on the metal surface, the water producing ureide bridges between two isocyanate groups and such bridges then forming complexes with metal oxide films.
>
> On the rubber interface, adhesion is thought to be due to solubility of isocyanates in the rubber and to secondary valence forces. With cellulose, bonding results from the unavoidable water present in the cellulose reacting preferentially with the isocyanate.
>
> Leather can be bonded by means of isocyanates by reaction between the amino groups of the leather and the isocyanate.

These German-developed adhesives were intensively studied by Allied countries [e.g., BIOS 629; BIOS 719; BIOS 1691; BIOS 1699] and came to be used around the world after the war.

Chapter 4

Creators and Creations in Earth and Space Science

Daher ist die Aufgabe nicht sowohl zu sehen was noch keiner gesehen hat, als bei Dem was Jeder sieht, zu denken was noch Keiner gedacht hat.	Therefore the problem is not so much, to see what no one has yet seen, but rather to think concerning that which everyone sees, what no one has yet thought.

Arthur Schopenhauer. 1851.
Parerga und Paralipomena: Kleine Philosophische Schriften.
Vol. 2, Section 76, p. 93. Berlin: A. W. Hayn.

This chapter gives an overview of some earth and space science innovations that have played major roles in the modern world and that were discovered or developed by scientists and engineers who were trained in the predominantly German-speaking central European research world in the nineteenth and early twentieth centuries.[1]

---

[1] In addition to specific references that are cited in different areas throughout this chapter, this chapter makes use of general biographical and project information from: ACLS 2000; Albrecht et al. 1992; Ash and Söllner 1996; Bar-Zohar 1967; Bower 1987; Bunch and Hellemans 2004; Challoner 2009; Cornwell 2003; Crim 2018; EB 1911, 2010; Gillispie 1970–1990; Gimbel 1990a; Glatt 1994; Hall 2019a; István Hargittai 2006, 2011; Linda Hunt 1991; Impey et al. 2008; Jacobsen 2014; Koertge 2007; Kurowski 1982; Lasby 1971; Lusar 1956, 1971; Medawar and Pyke 2000; Mick 2000; Murray 2003; Nachmansohn 1979; NDB 1953–2020; Neufeld 2012; Nouzille and Huwart 1999; O'Reagan 2014, 2019; Porter 1994; Charles Walker 1946; Peter Watson 2010; Weitensfelder 2009.

4.2. Paleontology

4.3. Ocean and hydrological science

4.4. Atmospheric science

4.5. Planetary science

4.6. Astrophysics

4.1 Geological Science

German-speaking scientists made a long string of discoveries in geological science and related fields, including:

4.1.1. Stratigraphy and continental drift

4.1.2. Geophysics

4.1.3. The Universal Transverse Mercator (UTM) for map coordinates

Outside observers were impressed and even envious of how seriously the whole German-speaking world took the field of geology. For example, in BIOS 948, *German Academic Geology*, visiting British scientists wrote after World War II:

> Geology was a subject formerly taught in German schools but was removed from the curriculum under the Hitler regime. It is, we understand, to be replaced and it is clear that teachers should receive sound geological training up to the necessary level at their Universities. [...]
>
> Strong representations have been made for a number of years that Geology should be a part of the normal science curriculum in British schools. In this respect, the team regard the proposed German curriculum as on a considerably wider basis than the existing British practice. [...]
>
> In prewar times, German geologists found employment in considerable numbers outside Germany[...]
>
> We were impressed with the high status of German mining and miners. There is a deep-routed tradition derived from the thousand years of their honourable history that has given the German miners a sense of self-esteem and a realisation of their high place in the community.

I have deliberately left a blank space where images of some creators or creations should go. Those are people or projects that I felt were important enough that they should definitely be shown in this book, yet I have not yet been able to locate a suitable image that I have permission to use, despite my searches in Europe and in the United States. If readers have any relevant images and could send them to me, I would be very grateful and will include them in future editions of this book. Even where a suitable photo cannot be located, I believe that leaving a blank space pays tribute both to the scientific importance of that creator or creation and to how that historical fact has been very nearly forgotten.

4.1.1 Stratigraphy and Continental Drift

Abraham Gottlob Werner (German states, 1749–1817, Fig. 4.1) developed stratigraphy, the scientific analysis of rock layers of increasing age with increasing depth. He also taught a large number of students, many of whom became highly influential geologists. *Encyclopaedia Britannica* called him the "father of German geology" [EB 1911].

Eduard Suess (Austrian, 1831–1914) discovered and correctly interpreted evidence for the Paleozoic southern supercontinent Gondwana and the adjacent Tethys Ocean (1861); see Fig. 4.2. Suess also proposed methods of measuring changes in ancient sea levels vs. time and was one of the first scientists to discuss the ecology of biospheres. Oxford University's *Biographical Dictionary of Scientists* summarized some of Suess's research accomplishments [Porter 1994, p. 651]:

> The outcome of these interests was *The Face of the Earth* 1885–1909, a massive work devoted to analysing the physical agencies contributing to the Earth's geographical evolution. Suess offered an encyclopedic view of crustal movement, of the structure and grouping of mountain chains, of sunken continents, and of the history of the oceans. He also made significant contributions to rewriting the structural geology of each continent.
>
> In many respects, Suess cleared the path for the new views associated with the theory of continental drift in the twentieth century. In view of geological similarities between parts of the southern continents, Suess suggested that there had once been a great supercontinent, made up of the present southern continents; this he named Gondwanaland, after a region of India. Wegener's work was later to establish the soundness and penetration of such speculations.

Alfred Wegener (German, 1880–1930) marshalled detailed evidence for his theory of continental drift (1912–1930) and also made major contributions to the understanding of polar air circulation. Wegener, shown in Fig. 4.3, was the son-in-law of Wladimir Köppen (p. 782). Wegener died while on an expedition to Greenland to gather more evidence for his theories. His ideas regarding continental drift became widely accepted and celebrated after his death [Greene 2015; Wegener 1966]. The *Encyclopedia Britannica* described Wegener's research [EB 2010]:

> German meteorologist and geophysicist who formulated the first complete statement of the continental drift hypothesis. [...]
>
> In about 1910 he began toying with the idea that in the Late Paleozoic era (about 250 million years ago) all the present-day continents had formed a single large mass, or supercontinent, which had subsequently broken apart. Wegener called this ancient continent Pangaea. [...]
>
> Wegener first presented his theory in lectures in 1912 and published it in full in 1915 in his most important work, *Die Entstehung der Kontinente und Ozeane* (*The Origin of Continents and Oceans*). He searched the scientific literature for geological and paleontological evidence that would buttress his theory, and he was able to point to many closely related fossil organisms and similar rock strata that occurred on widely separated continents, particularly those found in both the Americas and in Africa.

4.1.2 Geophysics

Emil Wiechert (German, 1861–1928) established the detailed study of the structure of the Earth and the behavior of different types of seismic waves passing through parts of the Earth; see Fig. 4.4. Specifically, he invented an improved seismograph, calculated how seismic waves propagate through the Earth, demonstrated evidence for layers within the Earth, and proposed that the Earth's core was made of iron. Wiechert was also one of several German-speaking scientists who discovered and analyzed the electron before the more famous work of J. J. Thomson (p. 863).

Wiechert was the first professor of geophysics in Germany and founded the world's first Institute of Geophysics at Göttingen University in 1898. In 1922, he also initiated the foundation of the German Geophysical Society (initially called the Deutsche Seismologische Gesellschaft). Wiechert attracted, taught, and collaborated with many younger scientists who made fundamental discoveries in geophysics, such as:

- Gustav Angenheister (German, 1878–1945, Fig. 4.5) studied surface waves from earthquakes, was the director of an observatory in Samoa for several years, and in 1928 became the successor of Wiechert as head of the Institute of Geophysics at Göttingen University.

- Ludwig Carl Geiger (Swiss, 1882–1966, Fig. 4.5) made many contributions to seismology, most notably by developing a method to determine the epicenter of an earthquake.

- Beno Gutenberg (German, 1889–1960) was one of Wiechert's greatest students at the Göttingen Institute of Geophysics, and he continued to conduct geophysics research after he obtained his doctorate in 1911. Gutenberg built upon all of the Institute's work up to that time by developing a system of quantifying earthquake energy, and also by making major contributions to the knowledge of the Earth's interior structure and convective circulation in the Earth's mantle (Fig. 4.6). Due to rising antisemitism in Germany, in 1930 Gutenberg moved to the California Institute of Technology and founded the Seismological Laboratory there. In the United States, the name of one of Gutenberg's American students, Charles Richter, became associated with the earthquake energy scale that had been developed by Gutenberg and that was based on decades of German seismological work at Göttingen. As a result, Richter's name has been immortalized with the "Richter scale," and the work of Gutenberg and all of his predecessors back to Emil Wiechert has been largely forgotten by the general public.

- Gustav Herglotz (German, 1881–1953, Fig. 4.5) worked with Emil Wiechert to develop equations for the velocities and travel times of seismic waves in the Earth (the Wiechert-Herglotz method). He also made many important contributions to applied mathematics and relativistic physics.

- Ludger Mintrop (German, 1880–1956, Fig. 4.5) invented seismic methods of exploring for oil and minerals, using his own specially designed vibrometers and seismographs. His work revolutionized oil drilling and minerals mining industries worldwide. During World War I, he developed seismic methods to locate the position of enemy artillery guns.

- Wilhelm Schlüter (German?, 1875–1902, Fig. 4.5) invented the clinograph for measuring changes in the angle of inclination of a slope. He used his new instrument to demonstrate that long waves from earthquakes are not linear oscillations that vibrate in one direction, but rather elliptical oscillations that vibrate around an elliptical pattern in two dimensions.

- Karl Bernhard Zoeppritz (German, 1881–1908, Fig. 4.5) developed the Zoeppritz equations for calculating the propagation and reflection of S and P seismic waves. He probably would have gone on to make many more important discoveries in geophysics, but unfortunately he died from an infection when he was only 26 years old.

Loránd Eötvös (Hungarian, 1848–1919) and Felix Vening Meinesz (Dutch, 1887–1966) developed increasingly sensitive gravitational gradiometers for mapping the mass distribution of underlying geological structures; see Fig. 4.7.

Alexander von Humboldt (Prussian, 1769–1859, Fig. 4.8) pioneered geomagnetic mapping, making and recording measurements of the Earth's magnetic field in his travels around the world [Wulf 2015]. He discovered that the strength of the magnetic field increases as one travels from the equator toward the poles. He also coined the term "physical geography," which later became known as geophysics.

Carl Friedrich Gauss (German states, 1777–1855) and Wilhelm Weber (German, 1804–1891), shown in Fig. 4.8, greatly improved geomagnetic mapping. They invented more accurate instruments for measuring the strength and direction of the magnetic field, established a society to make magnetic measurements around the world, and developed mathematical methods (potential theory) for analyzing the results to locate magnetic sources and to distinguish magnetic sources inside the Earth from those outside the Earth [Dunnington 1955]. (See also pp. 793, 828, 858, and 972.)

Julius Bartels (German, 1899–1964) and Gerhard Fanselau (German, 1904–1982) also made detailed studies of the Earth's magnetic field (Fig. 4.9).

Educated at Göttingen University and building upon all of that earlier German work on geomagnetism and geophysics, Walter Elsasser (German, 1904–1991) developed the dynamo model that explains how the Earth's magnetic field is generated by the Earth's core (Fig. 4.9). Though sadly little remembered now, Elsasser made strikingly innovative contributions to multiple scientific fields, including methods of calculating the "magic numbers" of protons and neutrons required to fill different energy levels of the atomic nucleus (p. 1535) [Rubin 1995]. The *Encyclopedia Britannica* praised his many revolutionary insights [EB 2010]:

> Elsasser received the Ph.D. from the University of Göttingen in 1927[...]
>
> While Elsasser was a graduate student he correctly predicted that a beam of electrons would be diffracted by a crystalline material; after the neutron was discovered, he predicted the same behaviour for neutrons. Independently of Nobel Prize winner Hans Bethe, Elsasser carried out important work on the likelihood of certain interactions between neutrons and atomic nuclei.
>
> Elsasser formulated what is called the dynamo model of the Earth's structure to account for the origin and properties of its magnetic field. He suggested that convection within the core, driven by the energy of radioactive decay, generates electric currents that

> intereract with concentric spherical shells of the Earth's mantle, which are rotating at different speeds, and that the Coriolis effect produces eddies at the boundaries of these shells.
>
> He also investigated the applicability of contemporary theoretical concepts of physics, especially quantum mechanics, to the biological sciences, presenting his views in *The Physical Foundation of Biology* (1958), *Atom and Organism* (1966), and *The Chief Abstractions of Biology* (1975).

As illustrated in Fig. 4.10, Victor Goldschmidt (Swiss, 1888–1947) founded the field of geochemistry, and Walter Hermann Bucher (German, 1888–1965) made major contributions to structural geology and paleontology.

4.1.3 Universal Transverse Mercator (UTM) for Map Coordinates

German-speaking creators also developed the Universal Transverse Mercator (UTM) projection system for map coordinates, which is now used worldwide for the Global Positioning System (GPS) [Buchroithner and Pfahlbusch 2016]. Official histories have claimed that the UTM system was developed by the United States after World War II, but cartographers Manfred Buchroithner and René Pfahlbusch discovered evidence that the UTM system was developed in Germany before and during World War II, and seized by the United States at the end of the war:

> Recent discoveries of Wehrmacht Maps in the Military Archive of the Federal Archive of Germany in Freiburg im Breisgau raised the motivation for further investigations into the history of the internationally employed Universal Transverse Mercator (UTM) projection which actually represents a prerequisite for the global use of Global Positioning System (GPS)—and thus of any type of navigation—instruments. In contrast to the frequently stated opinion that this map projection was first operationally used by U.S. Americans it turned out that presumably the first operational maps with indication of the orthogonal UTM grid were produced by German Wehrmacht officers prior to the post World War (WW) II triumph of this projection. Based on the authors' recent discoveries this article reveals some hitherto hardly known facts concerning the history of cartography of the 1940s. [...]
>
> With the complete military occupation of Germany through the Allied Forces in spring 1945 the largest part of the German geodetic documents and records stored in the Thuringian temporary evasion quarters of the "Reichsamt für Landesaufnahme" (RfL, Reich Office for Surveying) and the "Kriegskartenhauptamt" (Main Office for Military Maps) fell into the hands of the American troops. The U.S. Army Map Service (AMS) immediately examined these "German Materials, as they came to be called" (Cloud 2002, 264, cum lit.) and recognized its value. Since Thuringia was by negotiation provided as part of the Soviet Occupation Zone, all the material and the expert staff was evacuated to Bamberg in the American Occupation Zone. Directly after the war (Bamberg Conference in June 1945), with cooperation of staff members of the former RfL, a new geodetic "armaments program" for Europe began. Leading members of the mapping activities of the Deutsches Reich, last not least of the Reconnaissance Unit "Dora" and the "Forschungsstaffel zur besonderen Verwendung" (Research Squadron for Special Deployment) were, during the first months and years after the war, interrogated by the Americans.
>
> In his memoirs, Wolfgang Pillewizer (1911–1999), first member of the Reconnaissance Unit "Dora" and then of the "Forschungsstaffel zur besonderen Verwendung" (cf. Stams 2012) and as chair holder of cartography predecessor of the first author of this article, describes in considerable detail the interrogations of himself and also other members of the Reconnaissance Unit "Dora" and the "Research Squadron for Special Deployment" by OSS, the Office of Strategic Services, the then military secret service (Pillewizer 1986). In his book and later during oral communications with the prime author in the 1990s, he also mentioned that one task of the "Forschungsstaffel" was the mapping of possible "extension areas" of the Deutsches Reich, and that immediately after the war OSS chased him and subsequently kept him detained in Kransberg Castle, Germany,

over 16 months for interrogations about his cartographic activities in Eastern Europe and outside Europe (cf. also Häusler 2007b; Buchroithner, Koch, and Stams 2012). There, not only thematic but also geometric questions of the cartographic work were subject of the questioning. [...]

Early German research and development results were adopted by the Soviet Union in the 1930s and later by the USA and gained worldwide recognition—last not least through the introduction of the UTM system by the NATO member states in 1951. The end of the Cold War and the release of the military satellite navigation system of NATO for civilian purposes led to its final breakthrough. This implies that today almost all industrialized countries use for their authoritative map series a geodetic coordinate system which has its origin, for the most essential part, in Germany. In the twenty-first century, in a world of ubiquitous application of GPS at a global scale, UTM Projection became simply a *conditio sine qua non* for everyday life.

4.2 Paleontology

Scientists from the German-speaking world made many valuable contributions to areas of paleontology including:[2]

4.2.1. Animal and plant fossils

4.2.2. Hominid fossils

4.2.3. Biogeography

4.2.1 Animal and Plant Fossils

Friedrich von Alberti (German, 1795–1878), shown in Fig. 4.11, identified and characterized Triassic rock strata and their fossils, as well as the preceding large Permian-Triassic extinction event, and the following Triassic-Jurassic extinction event. He published the results of those studies in 1834. He also greatly improved salt mining and salt processing by introducing a process of steam heating.

Christian Leopold von Buch (German states, 1774–1853, Fig. 4.12) similarly characterized Jurassic rock strata and their fossils, and also explained igneous rock formation. He created the first geological map of Germany in 1826.

As shown in Fig. 4.13, Karl Häberlein (German?, 18??–19??), Hermann von Meyer (German states, 1801–1869), and Wilhelm Dames (German, 1843–1898) discovered and analyzed *Archaeopteryx* specimens, which are important transitional fossils for bird evolution (1861–1884) [Chambers 2002; Wellnhofer 2008]. Hermann von Meyer also discovered *Plateosaurus*, an important step in the evolution of sauropod dinosaurs, and Wilhelm Dames also studied whale evolution.

The American Council of Learned Societies described von Meyer's importance in the field of paleontology [ACLS 2000, p. 602]:

> His main scientific area of interest was the fossil vertebrates, and his chief work was *Fauna der Vorwelt* (4 vols., 1845). He considered all types of vertebrates and was one of the most distinguished scientists in the field; his descriptions were characterized by great accuracy and clarity of expression.

Ernst Stromer (German, 1871–1952, Fig. 4.14) led an important expedition to Egypt to excavate Cretaceous deposits, and he spent much of the rest of his career analyzing his finds in Germany. Through this material, Stromer discovered *Spinosaurus* and several other Cretaceous dinosaurs along with many non-dinosaur species. Unfortunately almost all of his fossil collection was destroyed when the Munich museum housing it was bombed by the Allies in 1944 [Nothdurft and Smith 2002; Probst 2015].

---

[2] Bowler 1993; Chambers 2002; Colbert 1984; Hesse 1924, 1937; Javanović-Kruspel 2015; Nothdurft and Smith 2002; Probst 2015; Wellnhofer 2008; Wulf 2015.

Louis Agassiz (Swiss, 1807–1873, Fig. 4.15) studied in Germany and worked in Switzerland before eventually moving to the United States, where he helped to build up the field of paleontology from his post at Harvard. He found and analyzed a wide variety of fossils over the course of his career.

Heinrich Ernst Beyrich (German, 1815–1896, Fig. 4.15) discovered many Cenozoic fossils and named the Oligocene epoch of the Cenozoic era.

Johanna "Tilly" Edinger (German, 1897–1967, Fig. 4.15) founded the field of paleoneurology, the study of brain structure and brain evolution from endocasts preserved inside some fossil skulls. Oxford University's *Biographical Dictionary of Scientists* emphasized the importance of Edinger's research [Porter 1994, p. 201]:

> Edinger was a leading figure in the field of twentieth-century vertebrate palaeontology and laid the foundations for the study of palaeoneurology. In her two great works *Die fossilen Gehirne* (Fossil Brains) (1929) and *The Evolution of the Horse Brain* (1948) she demonstrated that the evolution of the brain could be studied directly from fossil cranial casts.

Hanns Bruno Geinitz (German, 1814–1900, Fig. 4.15) collected and analyzed fossils from Europe, Asia, and North America, and discovered a wide variety of Paleozoic and Mesozoic species.

Friedrich von Hüne (German, 1875–1969, Fig. 4.15) discovered fossils of many new species of dinosaurs, other reptiles, and amphibians, and worked to reclassify previously discovered fossil species in a much more systematic fashion. Edwin Colbert, a curator of paleontology at the American Museum of Natural History, praised von Hüne's accomplishments [Colbert 1984, pp. 108–109]:

> Von Huene was wholeheartedly interested in the dinosaurs; during his lifetime he became one of the great authorities on these reptiles. [...]
>
> He has spent many decades in the study of fossil reptiles, with a singleness of purpose and a degree of industry that are truly amazing. The volume of his publications through the years is prodigious, and his contributions to our knowledge of fossil reptiles are numerous and significant. They include papers on reptilian relationships and classification, descriptions of dinosaurs from all over the world, investigations of various Mesozoic marine reptiles, especially ichthyosaurs, and other technical studies too numerous to mention. [...]
>
> He has been noted for his activity in the field, traveling all over the world to study and collect fossil reptiles—not only in his native Germany but also in other parts of Europe, in North America, in Brazil, in Argentina, in Africa, and in Asia.

Johanna “Tilly” Edinger (1897–1967) founded paleoneurology

Hanns Bruno Geinitz (1814–1900) discovered a wide variety of Paleozoic and Mesozoic fossils

Friedrich von Hüne (1875–1969) discovered many dinosaurs, other reptiles, and amphibians

Figure 4.15: Other creators who made important discoveries in paleontology included Louis Agassiz, Heinrich Ernst Beyrich, Johann Blumenbach, Johanna “Tilly” Edinger, Hanns Bruno Geinitz, and Friedrich von Hüne.

4.2.2 Hominid Fossils

Many important discoveries in human evolution were made by scientists from the greater German-speaking world.

Johann Blumenbach (German states, 1752–1840, Fig. 4.15) developed the foundations of the field of anthropology, studying the skeletal remains and evidence of the lifestyles of prehistoric humans worldwide.

Marie Eugène Dubois (Dutch, 1858–1940) discovered the first fossils of *Homo erectus* (dubbed "Java Man") in 1891; see Fig. 4.16. *Homo erectus* was a widespread and tremendously important ancestor of modern *Homo sapiens*. Franz Weidenreich (German, 1873–1948) and Ralph von Königswald (German, 1902–1982) discovered and analyzed additional *Homo erectus* fossils.

As shown in Fig. 4.17, in 1907 Otto Schoetensack (German, 1850–1912) and Daniel Hartmann (German?, 18??–19??) discovered the first fossils of *Homo heidelbergensis*, which was either a direct ancestor or a close cousin of modern humans.

Johann Fuhlrott (German, 1803–1877) and Hermann Schaaffhausen (German, 1816–1893) discovered the first fossils of *Homo neanderthalensis* in 1856 (Fig. 4.18). *Homo neanderthalensis* or Neanderthals were a sophisticated species of humans that existed in parallel with *Homo sapiens* for thousands of years, then disappeared for reasons that are still unclear.

Hugo Obermaier (German, 1877–1946) made important discoveries regarding the migrations, tools, and cave paintings of humans during the Ice Ages, as illustrated in Fig. 4.19.

4.2.3 Biogeography

As shown in Fig. 4.20, several creators made major contributions to the field of biogeography, or the worldwide distributions of modern species.

Alexander von Humboldt (Prussian, 1769–1859) collected and compared plant samples from around the world, as illustrated in Fig. 4.20. He published many books on his discoveries and thereby helped to establish the field of biogeography. He also made important measurements of geomagnetism in his travels around the world [Wulf 2015].

Christian Ehrenberg (German, 1795–1876) collected zoological, botanical, and microbiological specimens, and studied the comparative anatomy of samples from Europe, the Middle East, and around the world.

Richard Hesse (German, 1868–1944) published *Tiergeographie auf Ökologischer Grundlage* in 1924. Together with its 1937 revised English edition, *Ecological Animal Geography*, that book had an enormous impact in advancing the field of biogeography [Hesse 1924, 1937].

4.3 Ocean and Hydrological Science

German-speaking scientists made major contributions to ocean and hydrological sciences and related areas, including:[3]

4.3.1. Oceanography

4.3.2. The discovery and exploration of Antarctica

4.3.3. Evidence for the Ice Ages

4.3.1 Oceanography

Heinrich Georg von Boguslawski (German, 1827–1884, Fig. 4.21) coauthored the *Handbuch der Ozeanographie* [*Handbook of Oceanography*] with Otto Krümmel. It appeared in 1884–1887 in two large volumes covering all major aspects of ocean spatial distribution, physical properties, chemistry, circulation, etc., and became the standard reference work on the subject for many decades, including later updates.

Carl Chun (German, 1852–1914, Fig. 4.21) led expeditions in the *Valdivia* research ship (Fig. 4.23) and made important discoveries regarding deep sea life, marine invertebrates, and subarctic seas.

Carl Wilhelm Correns (German, 1893–1980, Fig. 4.21) was the world's leading expert in marine sediments [BIOS 1368]. He collected sediments on marine expeditions in the 1920s, and used new methods such as X-ray diffraction to analyze them in his laboratory in the 1930s. He was the son of the biologist Karl Correns (p. 107). The American Council of Learned Societies described some of his accomplishments [ACLS 2000, pp. 209–210]:

> A pioneer in modern sedimentary petrology, he found that clays are not amorphous substances but mixtures of well-defined crystalline minerals such as kaolinite, halloysite, montmorillonite, and mica materials. With samples from the bottom of the South Atlantic, he developed methods for dividing sediments into grain size classes that could be investigated by optical microscopy, X-ray diffraction, and chemical analysis.

Albert Defant (Austrian, 1884–1974, Fig. 4.21) founded the field of physical oceanography and was an expert on the physics of the ocean, the atmosphere, and the interactions between the two. He was one of the main scientists on the *Meteor* oceanographic research ship.

Günter Dietrich (German, 1911–1972, Fig. 4.21) helped to refine the comprehensive understanding of ocean tides, currents, and circulation.

---

[3] von Boguslawski and Krümmel 1884–1887; Bowler 1993; Spiess 1985.

Felix Anton Dohrn (German, 1840–1909, Fig. 4.21) established the model of marine biological research stations, especially with a station on the Gulf of Naples (Stazione Zoologica, initiated in 1871). The American Council of Learned Societies described the importance of his work [ACLS 2000, p. 256–257]:

> Primary contribution was the establishment of the Zoological Station in Naples: not only the first laboratory set up specifically for marine studies, but also the first institute formally organized for the sole pursuit of research. The station was conceived by Dohrn in 1870, and the doors opened in February 1874. [...M]any important pioneering experimental investigations were carried out. Especially significant were studies in comparative physiology and experimental embryology, which became the foundations of whole new sciences.

Ernst Ehrenbaum (German, 1861–1942, Fig. 4.22) made major contributions to systematic ichthyology as well as the study of marine invertebrates.

Vagn Walfrid Ekman (1874–1954, Fig. 4.22) was Swedish but worked very closely with German expeditions, providing oceanographic measuring instruments and conducting theoretical calculations to compare with the measured data. Many oceanographic properties are named after him: the Ekman layer, Ekman number, Ekman pumping, Ekman spiral, Ekman transport, etc.

Otto Krümmel (German, 1854–1912, Fig. 4.22) coauthored the *Handbuch der Ozeanographie* [*Handbook of Oceanography*] with Heinrich Georg von Boguslawski, completing the first edition after von Boguslawski's death and then updating it later. Some of Krümmel's greatest contributions involved the study of ocean currents and circulation patterns (Fig. 4.24).

Alfred Merz (Austrian, 1880–1925, Fig. 4.22) was a pioneer of oceanography and was the first chief scientist for the *Meteor* research ship (Fig. 4.23).

Friedrich (Fritz) Spiess (German, 1881–1959, Fig. 4.22) championed the funding and execution of oceanographic research, and he planned and commanded the expeditions of the *Meteor* research ship.

Georg Wüst (German, 1890–1977, Fig. 4.22) studied ocean circulation and was one of the main scientists on the *Meteor* research ship.

4.3.2 Antarctica

German-speaking scientists discovered Antarctica and played a major role in its exploration [Lüdecke 2015; Schön 2004].

Fabian Gottlieb von Bellingshausen (Baltic German, 1778–1852) led an expedition that discovered Antarctica in 1820. He proceeded to circumnavigate Antarctica and to make contact with its coastline at several points along the way; Fig. 4.25 illustrates the route of his expedition. Bellingshausen Island and Bellingshausen Sea near Antarctica are named after him.

Erich von Drygalski (German, 1865–1949, Fig. 4.26) led groups that explored Greenland during 1891–1893 and Antarctica during 1901–1903. In Antarctica, his expedition discovered and named Kaiser Wilhelm II Land and the Gaussberg volcano, and was the first to use a balloon for Antarctic exploration and photography. Drygalski Island in Antarctica is named after him.

Wilhelm Filchner (German, 1877–1957, Fig. 4.26) headed an Antarctic expedition during 1911–1912 that discovered the Luitpold Coast and mapped part of Antarctica. The Filchner-Ronne Ice Shelf in the Antarctic is named for him (and the much later U.S. Ronne expedition from 1947–1948).

Alfred Ritscher (German, 1879–1963, Fig. 4.26) led a major Antarctic expedition during 1938–1939 that mapped a large part of Queen Maud Land. Ritscher Peak and Ritscher Upland in Antarctica are named after him.

4.3.3 Ice Ages

As illustrated in Fig. 4.27, Eduard Brückner (German, 1862–1927) and Albrecht Penck (German, 1858–1945) amassed and correctly interpreted a huge amount of evidence for the Ice Ages, especially from the Alps, from 1901 onward. In 1909, they published their results as the landmark three-volume work, *Die Alpen im Eiszeitalter* [*The Alps in the Ice Age*].

4.4 Atmospheric Science

As shown by the examples in Figs. 4.28–4.34, many creators from the German-speaking world made major discoveries in atmospheric science.[4]

Richard Assmann (German, 1845–1918, Fig. 4.28) published the first weather map for Germany in 1880, invented the Assmann aspiration psychrometer around 1890, and discovered the stratosphere in 1902. He was a strong and effective advocate for meteorology research and education.

Arthur Berson (German, 1859–1942, Fig. 4.28) made measurements of atmospheric conditions and human physiology at high altitudes, and led expeditions to study weather conditions in the Arctic, South America, Africa, and other regions.

Wilhelm von Bezold (German, 1837–1907, Fig. 4.28) made important discoveries regarding atmospheric thermodynamics and thunderstorms, as well as optical illusions (the Bezold effect and the Bezold–Brücke shift).

C. H. D. Buys Ballot (Dutch, 1817–1890, Fig. 4.28) studied the direction of air flow in weather systems (now known as the Buys Ballot law) and the effect of the annual cycle on Earth's atmospheric temperatures (now known as the Buys Ballot table). Even the American Council of Learned Societies deemed his work especially noteworthy, over a century after his death [ACLS 2000, p. 158]:

> [H]is chief accomplishment was to help shape the new field of meteorology by emphasizing and himself collecting data from the widest possible network of simultaneous observations.

Paul Crutzen (Dutch, worked in Germany, 1933–, Fig. 4.28) was instrumental in analyzing and predicting damage to the ozone layer by pollution, climate change effects caused by burning fossil fuels, and the possibility of a nuclear winter created by dust from numerous explosions. He won the Nobel Prize in Chemistry in 1995 for his work on the ozone layer. Professor Ingmar Grenthe of the Royal Swedish Academy of Sciences noted [https://www.nobelprize.org/prizes/chemistry/1995/ceremony-speech/]:

> In 1970 Paul Crutzen demonstrated that nitrogen oxides, formed during combustion processes, could affect the rate of ozone depletion in the stratosphere. He suggested that dinitrogen monoxide, popularly known as "laughing gas" and formed through microbiological processes in the ground, could have the same effect. He has also studied the formation of ozone in the lower atmosphere. Ozone is one ingredient of "smog," which is formed by the influence of solar radiation on air pollutants, especially exhaust gases from motor vehicles and other combustion systems. Whereas stratospheric ozone is a prerequisite for life, tropospheric ozone is strongly toxic and harmful to most organisms, even in small quantities.

---

[4] Bowler 1993; von Hann 1887; von Hann and Süring 1926; Haurwitz 1941.

Julius von Hann (Austrian, 1839–1921, Fig. 4.28) was arguably the founder of systemic global meteorology. Figures 4.32–4.32 show a few pages from his *Atlas der Meteorologie* (1887) giving average isotherms, isobars, winds, and rainfall worldwide. Julius von Hann and Reinhard Süring wrote the *Lehrbuch der Meteorologie*, which became the standard textbook for generations of meteorology students. The American Council of Learned Societies noted [ACLS 2000, p. 394]:

> Hann was one of the most prominent meteorologists of his day. His importance rested less on the creation of new theoretical concepts than on his efforts to coordinate empirical and theoretical results into a coherent structure. [...] He was a driving force in the establishment of mountain observatories, where he studied upper-air data from many different aspects. He produced the first comprehensive climatologies of both the tropics and the polar regions.

Bernhard Haurwitz (German, 1905–1986, Fig. 4.29) received his Ph.D. in meteorology and geophysics from the University of Leipzig in 1927, worked there after graduating, and then moved to the United States in late 1932 due to rising antisemitism in Germany. He helped to bring German methods of meteorology to the United States. Haurwitz taught at MIT and New York University and wrote *Dynamic Meteorology*, which became the standard reference on the subject.

Hugo Hergesell (German, 1859–1938, Fig. 4.29) organized the regular collection of temperature, humidity, and pressure data by balloons at different altitudes in order to improve weather forecasts.

Karl Jelinek (Austrian, 1822–1876, Fig. 4.29) studied both meteorology and geomagnetism, combining measurements with new types of instruments and sophisticated mathematical analysis to obtain important new results.

Joseph Kölzer (German, 1883–1970, Fig. 4.29) established the field of military meteorology before World War I and continued to develop that area until after World War II. He also studied the propagation of sound waves in different layers of the atmosphere.

As shown in Fig. 4.33, Wladimir Köppen (German, 1846–1940) developed a detailed system of climate classification (how wet/dry and how hot/cold a region tends to be) that is still in use, with subsequent improvements by Rudolf Geiger (German, 1894–1981) [Geiger 1950; Köppen 1955]. Wladimir Köppen was the father-in-law of Alfred Wegener (p. 738), and Rudolf Geiger was the brother of Hans Geiger (p. 1520). The *Encyclopedia Britannica* described the importance of Köppen and his work [EB 2010]:

> German meteorologist and climatologist best known for his delineation and mapping of the climatic regions of the world. He played a major role in the advancement of climatology and meteorology for more than 70 years. His achievements, practical and theoretical, profoundly influenced the development of atmospheric science. [...]
>
> A climax in geographical climatology was reached in 1900 when Köppen introduced his mathematical system of climatic classification. Each of five major climate types was assigned a mathematical value according to temperature and rainfall. Since then, many of the systems introduced by other scholars have been based on Köppen's work. [...]

> In 1927 he undertook, with Rudolph Geiger, the editorship of a five-volume *Handbuch der Klimatologie* ("Handbook of Climatology"), which was nearly completed when he died. [...]
>
> Köppen was one of the last scholars of an era when an erudite man could attain competence in, and make significant contributions to, many branches of natural science.

As illustrated in Fig. 4.34, Auguste Piccard (Swiss, 1884–1962) and Paul Kipfer (Swiss, 1905–1980) studied the upper atmosphere and cosmic rays using their own specially designed high-altitude balloon with a pressurized crew compartment.

Reinhard Süring (German, 1866–1950, Fig. 4.29) made important discoveries regarding clouds, atmospheric radiation, the upper atmosphere, and high-altitude physiology. He and Julius von Hann wrote the *Lehrbuch der Meteorologie*, which became the standard textbook for generations of meteorology students.

4.5 Planetary Science

German-speaking scientists made a large number of important discoveries in planetary science [North 1995], including:

4.5.1. The heliocentric nature and orbits of the solar system

4.5.2. Moon and Mars maps

4.5.3. Asteroids

4.5.4. The outer solar system

For related contributions by German-speaking scientists to space travel and exploration, see Sections 9.7–9.10.

4.5.1 Heliocentric Solar System and Planetary Orbits

Although the German-speaking research world became more established after 1800 or so, one cannot cover planetary science without mentioning three very important creators from before that time:

Nicolaus Copernicus (Prussian, 1473–1543, Fig. 4.35) proposed that the planets orbit around the sun and conducted other work on astronomy and the design of scientific instruments. The scientific historian John North explained [North 1995, pp. 280–281]:

> Copernicus' greatest work, *De revolutionibus orbium caelestium* (On the Revolutions of the Celestial Spheres), was his definitive statement. It was completed at the very end of his life (1543) and differed in several technical respects from the brief sketch, which was probably written around 1510 (and certainly not later than 1514). The sketch contains a statement that the calculations in it are reduced to the meridian of Cracow, which he took to be the same as that of Frombork. In arguing that the Earth revolves around the Sun like any other planet, he introduced the names of authorities that he knew would carry weight in his own time, namely the Pythagoreans.

Tycho Brahe (Danish but educated and worked in the German-speaking world, 1546–1601, Fig. 4.36) made detailed astronomical observations that were used by Johannes Kepler to calculate planetary orbits.

Johannes Kepler (Weil der Stadt, 1571–1630, Fig. 4.37) worked out the physics of planetary orbits, which are slightly elliptical and not perfectly circular as Copernicus had previously assumed. Kepler also conducted other scientific research, including publishing a star catalog/astronomy handbook (*Rudolphine Tables*), describing the hexagonal close-packed symmetry of some crystals, and studying optics. Oxford University's *Biographical Dictionary of Scientists* praised Kepler's approach and accomplishments [Porter 1994, pp. 385, 387]:

> Kepler [...] was a German astronomer who combined great mathematical skills with patience and an almost mystical sense of universal harmony. He is particularly remembered for what are now known as Kepler's laws of motion. These had a profound influence on Newton and hence on all modern science. Kepler was also absorbed with the forces that govern the whole universe and he was one of the first and most powerful advocates of Copernican heliocentric (Sun-centred) cosmology.
>
> [...H]e finally completed the Rudolphine Tables. They appeared in 1627 and brought Kepler much popular acclaim. These were the first modern astronomical tables, a vast improvement on previous attempts of this kind, and they enabled astronomers to calculate the positions of the planets at any time in the past, present or future. The publication also included other vital information, such as a map of the world, a catalogue of stars, and the latest aid to computation, logarithms.
>
> Kepler wrote the first science-fiction story, *Solemnium*, which described a man who travelled to the Moon. It was published in 1631, a year after his death, although it had been written 20 years earlier. Kepler was a remarkable man and a brilliant scientist. He kept a steady eye on what he saw as his true vocation as a 'speculative physicist and cosmologist' and, despite living in times of political unrest and religious turmoil, was never swayed by religious bigotry or political pressures. His new astronomy provided the basis on which Newton and others were to build, and to this day his three laws of motion are considered to be the basis of our understanding of the Solar System.

As shown in Fig. 4.38, Milutin Milanković (or Milankovitch, Serbian but educated and worked in Austria, 1879–1958) worked out how periodic changes in the Earth's orbit and axis affect its climate (Milanković or Milankovitch cycles). He also studied similar effects for Mercury, Venus, the Moon, and Mars.

4.5.2 Moon and Mars Maps

Creators who made important early detailed maps of the Moon and Mars included (Fig. 4.39):

Johann Hieronymus Schröter (German states, 1745–1816) created a Moon map in 1791 and a Mars map in 1800. The American Council of Learned Societies noted [ACLS 2000, p. 789]:

> The observatory he built and equipped at Lilienthal was a center of astronomical research for thirty years, becoming world-famous for the excellence of its instruments. First to observe the surface of the moon and the planets systematically over a long period; discovered and named the lunar rills. He had important influence on Harding, Bessel, and J. F. J. Schmidt.

Wilhelm Beer (Prussian, 1797–1850) and Johann Heinrich von Mädler (German, 1794–1874) produced a highly detailed Moon map during the period 1834–1837 (Fig. 4.40) and the best Mars map then available during the period 1830–1840 (Fig. 4.41).

Johann Friedrich Julius Schmidt (German, 1825–1884) created a Moon map even more detailed than that of Beer and Mädler during the period 1858–1874.

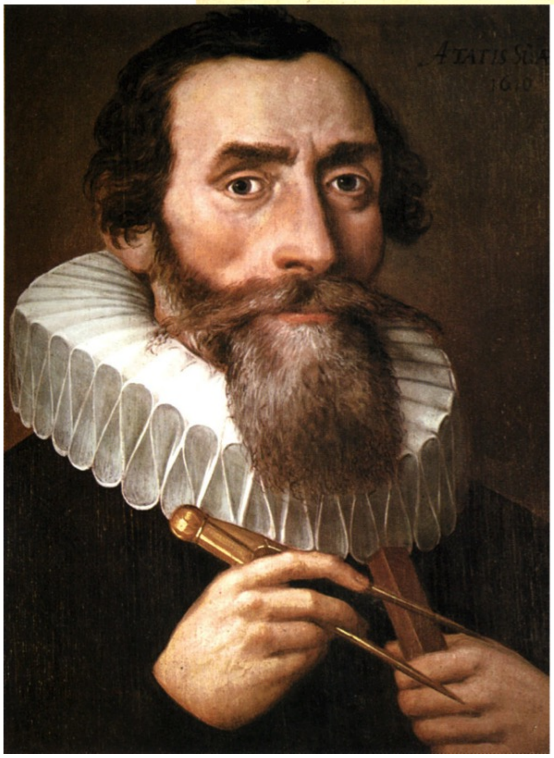
ANNO MDCXVIII.



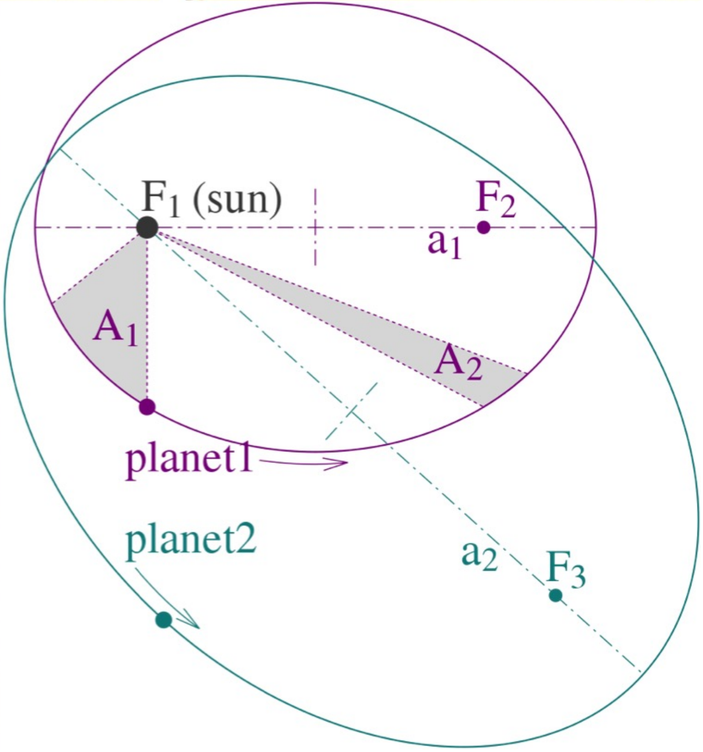


Figure 4.37: Johannes Kepler calculated the elliptical orbits of planets in the solar system.

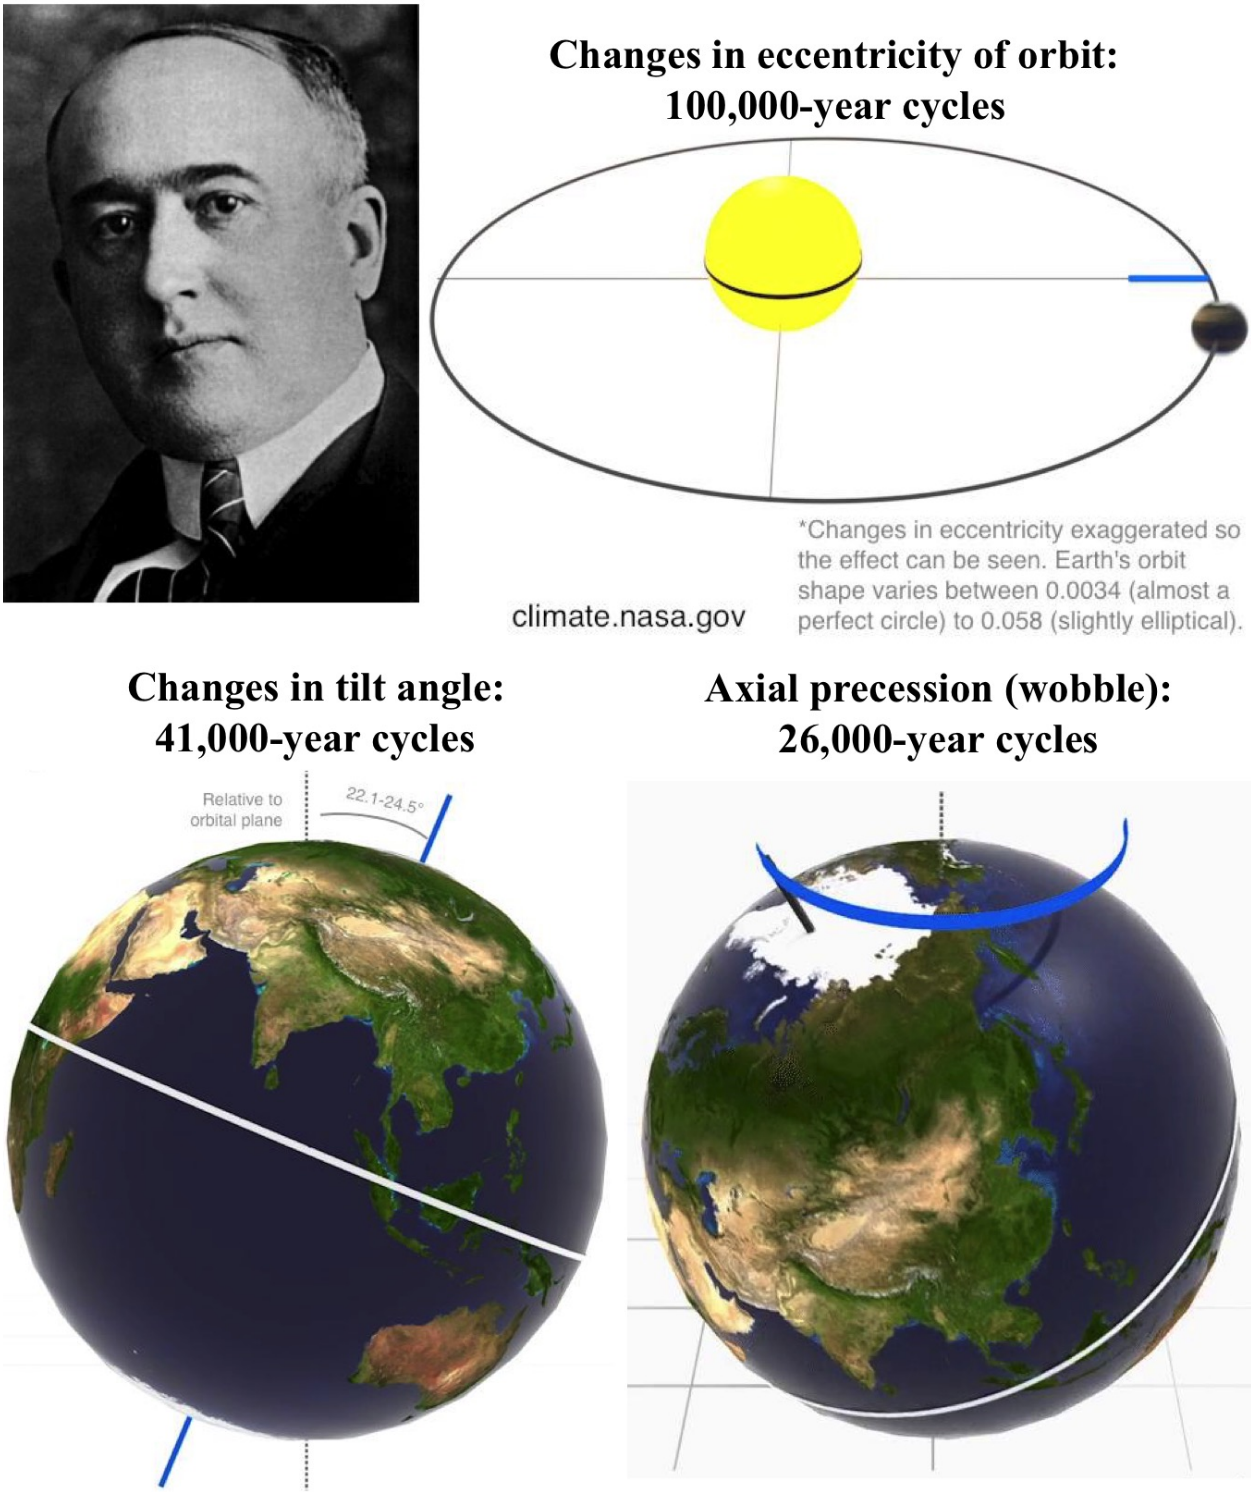
Milutin Milanković (1879–1958) worked out how periodic changes in the Earth's orbit and axis affect its climate (Milanković cycles). He studied similar effects for Mercury, Venus, the Moon, and Mars.



Changes in eccentricity of orbit: 100,000-year cycles

*Changes in eccentricity exaggerated so the effect can be seen. Earth's orbit shape varies between 0.0034 (almost a perfect circle) to 0.058 (slightly elliptical).

climate.nasa.gov

Changes in tilt angle: 41,000-year cycles

Axial precession (wobble): 26,000-year cycles

Figure 4.38: Milutin Milanković (or Milankovitch) worked out how periodic changes in the Earth's orbit and axis affect its climate (Milanković or Milankovitch cycles). He also studied similar effects for Mercury, Venus, the Moon, and Mars.

4.5.3 Asteroids

As shown in Fig. 4.42, Ernst Chladni (German states, 1756–1827) discovered and published (in 1794) detailed evidence that meteorites come from space [Chladni 1794]. He also spent much of his career investigating the physics of vibrations, sound waves, and musical instruments.

German-speaking creators discovered many major asteroids, including the largest asteroids in the main asteroid belt between Mars and Jupiter (Figs. 4.43–4.46).

Franz Xaver von Zach (Hungarian, 1754–1832) organized astronomical searches for asteroids and was one of the astronomers (along with Heinrich Olbers, Carl Friedrich Gauss, and Giuseppe Piazzi) to spot the largest asteroid, Ceres, in 1801.

Heinrich Olbers (German states, 1758–1840) was one of the astronomers who spotted Ceres in 1801. He also discovered the very large asteroids Pallas in 1802 and Vesta in 1807. He discovered Olbers' comet in 1815, and proposed Olbers' paradox (Why is the night sky dark if there are an infinite number of stars in every direction, if you look far enough?) in 1823. Olbers also aided the career of the young Friedrich Bessel. For much of his life, Olbers was actually a practicing ophthalmologist in Bremen; he was also an early proponent of smallpox vaccination.

Carl Friedrich Gauss (German states, 1777–1855) developed revolutionary new methods for calculating orbits that led to the discovery and tracking of Ceres in 1801. He also calculated other asteroid orbits and developed methods of accounting for the perturbations of asteroid orbits by planets [Dunnington 1955]. (See also pp. 740, 828, 858, and 972.)

At the University of Göttingen, Karl Ludwig Harding (German states, 1765–1834) discovered the very large asteroid Juno in 1804. He also discovered several comets, created an important star catalog, and studied the behavior of variable stars.

Hermann Goldschmidt (German states, 1802–1866) found 14 asteroids and also made other astronomical discoveries regarding variable stars and atmospheric distortions during solar eclipses. In addition, he had a long and successful career as a painter.

Karl Robert Luther (German, 1822–1900) spent several decades working at an observatory in Düsseldorf; he discovered 24 asteroids.

Johann Palisa (Austrian, 1848–1925) was director of the Austrian Pula and Vienna observatories. He discovered 122 asteroids as well as some comets, and later collaborated with Maximilian Wolf on a photographic star atlas.

Friedrich Schwassmann (German, 1870–1964) worked at observatories in Potsdam and Hamburg, where he discovered 22 asteroids and 4 comets.

Maximilian Wolf (German, 1863–1932) was an important pioneer of astrophotography, and used that technique to discover hundreds of asteroids, including the first of the large population of 'Trojan asteroids' in orbit near Jupiter. He also discovered several nebulae, studied sunspots, carried out observations of Halley's comet, and invented the stereo-comparator tool for astronomical observations. Oxford University's *Biographical Dictionary of Scientists* explained the importance of Wolf's innovations [Porter 1994, p. 732]:

> One of his most successful innovations was a technique for discovering large numbers of asteroids. Until this time, asteroids had always been discovered visually[...] Wolf arranged for time-lapse photographs to be taken, using a camera mounted on a telescope whose clock mechanism followed as exactly as possible the proper motion of the 'fixed stars'. On the developed plate, the stars would appear as discrete spots—the size being a function of the star's magnitude—whereas any asteroids present would appear as short streaks in the foreground.
>
> The first asteroid Wolf discovered using this technique was number 323, afterwards named Brucia. He subsequently discovered more than 200 other asteroids using the same method. In September 1903, he discovered a special asteroid, number 588, later named Achilles. Its particular significance was that it was the first of the so-called 'Trojan satellites' whose orbits are in precise synchrony with that of Jupiter's; they form a gravitationally stable configuration between Jupiter and the Sun.

Many of Wolf's students at the University of Heidelberg made their own discoveries and had very productive careers in astronomy, including for example:

- Alfred Bohrmann (German, 1904–2000) discovered 9 asteroids and made extensive observations of many others.
- Paul Götz (German, 1883–1962) identified 20 asteroids.
- Joseph Helffrich (German, 1890–1971) found 13 asteroids.
- Franz Kaiser (German, 1891–1962) discovered 21 asteroids.
- August Kopff (German, 1882–1960) identified 68 asteroids and several comets.
- Karl Wilhelm Reinmuth (German, 1892–1979) found 395 asteroids plus some comets.

Antonín Mrkos (Czech/Austrian, 1918–1996) was one of the leading astronomers in Czechoslovakia; he discovered 274 asteroids and 13 comets.

Paul Wild (Swiss, 1925–2014) worked at the University of Bern and also with Fritz Zwicky at Caltech (p. 813). He found 94 asteroids, plus 41 supernovae and at least 7 comets.

Johann M. Baur (German, 1930–2007) founded a private observatory in northern Italy and discovered 15 asteroids.

Working at the Karl Schwarzschild Observatory in Tautenburg, Freimut Börngen (German, 1930–2021) discovered 538 asteroids and also made extensive studies of galaxies.

4.5.4 Outer Solar System

Creators from the greater German-speaking world made many major discoveries regarding the planets, moons, and comets of the outer solar system.

Johann Encke (German states, 1791–1865) and Theodor von Oppolzer (Austrian, 1841–1886) each carefully worked out the detailed orbits of many planets, asteroids, and comets (Fig. 4.47).

Friedrich Wilhelm Herschel (Hanover, 1738–1822, Fig. 4.48) discovered the planet Uranus in 1781, as well as two of its moons: Oberon (1787) and Titania (1787). He also discovered two additional moons of Saturn (Enceladus and Mimas, both in 1789) and studied the behavior of sunspots.

Friedrich Wilhelm Herschel's sister, Caroline Herschel (Hanover, 1750–1848), worked with him in those endeavors and also composed a very important early star catalog [Hoskin 2011; Lemonick 2008].

Friedrich Wilhelm Herschel's son, John Herschel (1792–1871), later discovered several other moons of Saturn and Uranus and conducted important research in other scientific fields.

In 1782, Johann Bode (German states, 1747–1826, Fig. 4.49) named and worked out the orbit of the planet Uranus following Friedrich Wilhelm Herschel's discovery.

Johann Galle (German, 1812–1910, Fig. 4.49) discovered the planet Neptune in 1846 [Galle and Wattenberg 1963].

Gerard Kuiper (Dutch, 1905–1973, Fig. 4.49) discovered the methane atmosphere of Saturn's moon Titan (1944), carbon dioxide in the atmosphere of Mars (1947), Uranus's moon Miranda (1948), Neptune's moon Nereid (1949), and evidence for the Kuiper belt of comets orbiting beyond Neptune (1951). The astronomer Carl Sagan eulogized him [Sagan 1980, p. 143]:

> Gerard Peter Kuiper, who in the 1940's and 1950's was the world's only full-time planetary astrophysicist. The subject was then considered by most professional astronomers to be at least slightly disreputable[...] I am grateful to have been Kuiper's student.

Jan Oort (Dutch, 1900–1992, Fig. 4.60) proposed the existence of the Oort cloud of comets in the outer reaches of our solar system.

4.6 Astrophysics

Scientists from the German-speaking world played a dominant role in the development of astrophysics, including:

4.6.1. Cosmic rays

4.6.2. Stellar physics

4.6.3. Maps of stars and galaxies

4.6.4. Cosmology

4.6.1 Cosmic Rays

Cosmic rays are high-energy radiation that is emitted by the sun or other objects further out in space and that strikes the Earth's atmosphere, which mostly shields the Earth's surface from the rays [L'Annunziata 2016; North 1995].

German-speaking creators made most of the major discoveries regarding cosmic rays (Figs. 4.50–4.51).

Theodor Wulf (German, 1868–1946) created electroscopes for measuring radiation (Fig. 4.51) and demonstrated in 1910 that they detected more radiation from high on the Eiffel Tower than on the ground, suggesting that radiation was coming from space.

Victor Franz Hess (Austrian, 1883–1964) carried some of Theodor Wulf's electroscopes up in his 1912 balloon flight to measure cosmic rays, and showed that the measured cosmic ray radiation increased with altitude (Fig. 4.51). Hess won the Nobel Prize in Physics in 1936 for this work. Professor H. Pleijel, Chairman of the Nobel Committee for Physics of the Royal Swedish Academy of Sciences, praised Hess's discovery [https://www.nobelprize.org/prizes/physics/1936/ceremony-speech/]:

> Professor Hess. By virtue of your purposeful researches into the effects of radioactive radiation carried out with exceptional experimental skill you discovered the surprising presence of radiation coming from the depths of space, i.e. cosmic radiation. As you have proved, this new radiation possesses a penetrating power and an intensity of previously unknown magnitude; it has become a powerful tool of research in physics, and has already given us important new results with respect to matter and its composition. The presence of this cosmic radiation has offered us new, important problems on the formation and destruction of matter, problems which open up new fields for research. We congratulate you on your fine achievements.

Werner Kolhörster (German, 1887–1946) conducted more thorough balloon experiments in 1913–1914 and obtained more accurate data on cosmic ray radiation vs. altitude (Fig. 4.51).

Erich Regener (German, 1881–1955) developed improved radiation detectors and related instruments and launched them first in balloons and later in rockets.

Eduard Gottfried Steinke (German, 1899–1963) measured cosmic rays of different energies.

Georg Pfotzer (German, 1909–1981) was a student of Erich Regener and collaborated with him in his experiments.

Auguste Piccard (Swiss, 1884–1962) and Paul Kipfer (Swiss, 1905–1980) measured cosmic ray intensities up to the highest altitudes then possible in a balloon (Fig. 4.34).

For more information on the development of radiation detection methods in the German-speaking world, see Sections 8.1–8.2.

The graphs show Victor Hess's 1912 data on the measured cosmic ray radiation vs. altitude, and Werner Kolhörster's more accurate 1913–1914 data.

4.6.2 Stellar Physics

As illustrated in Fig. 4.52, stars such as the sun create such intense heat and pressure in the central core that they convert hydrogen into helium plus lots of energy. There are two parallel processes for that conversion, proton-proton fusion reactions and carbon-catalyzed fusion reactions.

Figures 4.53–4.54 show some of the creators who made major discoveries in stellar physics.[5]

Walter Baade (German, 1893–1960) identified and studied different types of stars.

Hans Bethe (German, 1906–2005) worked out the major fusion reactions in stars, for which he won the Nobel Prize in Physics in 1967 (p. 1542).

Ludwig Biermann (German, 1907–1986) studied the solar wind of charged particles streaming outward from the sun.

Robert Emden (Swiss, 1862–1940) developed the Emden equation describing the spatial variation of pressure inside a star.

Joseph von Fraunhofer (German states, 1787–1826) performed spectral analyses of the sun.

Fritz Houtermans (German, 1903–1966) first worked out some of the fusion reactions and reaction rates in stars.

Rudolph Minkowski (German, 1895–1976) used astrophotography to study supernovae.

J. Robert Oppenheimer (1904–1967) calculated the conditions involved in stellar collapse at the end of a star's life. Oppenheimer was born in the United States but had a German father and second-generation German-American mother, was raised speaking German, repeatedly visited family in Germany during his childhood, and received his Ph.D. in Germany under Max Born at Göttingen.

Samuel Heinrich Schwabe (German, 1789–1875) studied sunspots.

Martin Schwarzschild (German, 1912–1997) made major contributions to our understanding of stellar structure and evolution.

Hermann Carl (or Karl) Vogel (German, 1841–1907) performed spectral analyses of stars. Among other findings, he discovered spectroscopic binary stars—pairs of mutually orbiting stars that are so close together that they appear as one point of light when viewed from Earth, yet that can be distinguished from each other by the spectra of light that they emit.

Carl Friedrich von Weizsäcker (German, 1912–2007) worked out the major fusion reactions in stars.

For more information on fusion reactions, see Section 8.6.

4.6.3 Maps of Stars and Galaxies

Friedrich Bessel (German states, 1784–1846) developed the parallax method of measuring distances to stars (see Fig. 4.55), as well as Bessel mathematical functions. Based on geodetic observations, he approximated the figure of the Earth, and in 1841 he established the Bessel ellipsoid, which was used as an important geodetic reference system for over a century. His theory of observational errors was also highly influential in the physical sciences. The *Encyclopedia Britannica* explained the impact of Bessel's work [EB 2010]:

> Bessel was a scientist whose works laid the foundations for a better determination than any previous method had allowed of the scale of the universe and the sizes of stars, galaxies, and clusters of galaxies. In addition, he made fundamental contributions to accurate positional astronomy, the exact measurement of the positions of celestial bodies; to celestial mechanics, dealing with their movements; and to geodesy, the study of the Earth's size and shape. Further, he enlarged the resources of pure mathematics by his introduction and investigation of what are now known as Bessel functions, which he used first in 1817 to investigate the very difficult problem of determining the motion of three bodies moving under mutual gravitation. Seven years later he developed Bessel functions more fully for the treatment of planetary perturbations. Much credit for the final establishment of a scale for the universe in terms of solar system and terrestrial distances, which depends vitally on accurate measurement of the distances of the nearest starts from the Earth, must go to Bessel.

The multigenerational Baltic German Struve family of astronomers included (Fig. 4.56):

- Friedrich Georg Wilhelm von Struve (1793–1864), the son of German math teacher Jacob Struve (1755–1841), measured the distances to many stars using Bessel's parallax method, and also produced a catalog of binary stars (pairs of stars orbiting each other).

- Otto Wilhelm von Struve (1819–1905), the son of Friedrich Georg Wilhelm von Struve, made many important astronomical observations, including precession measurements for the solar system.

- Karl Hermann von Struve (1854–1920), a son of Otto Wilhelm von Struve, made detailed measurements of the positions of many moons and stars, and also devised the mathematical Struve function in 1882.

- Gustav Wilhelm Ludwig von Struve (1858–1920), another son of Otto Wilhelm von Struve, measured accurate positions of stars and the rotation rate of our Milky Way galaxy.

- Georg Otto Hermann Struve (1886–1933), the son of Karl Hermann von Struve, carefully measured the orbits of several moons of Saturn and Uranus. He also made important observations of stars and asteroids.

- Otto Struve (1897–1963), the son of Gustav Wilhelm Ludwig von Struve, studied interstellar matter and stellar physics.

Creators such as Friedrich Argelander (German, 1799–1875), Eduard Schönfeld (German, 1828–1891), Adalbert Krüger (German, 1832–1896), and Robert Trümpler (Swiss, 1886–1956) composed important catalogs of stars that are visible from Earth; see Fig. 4.57. Figure 4.58 shows examples of star catalogs by Argelander from 1843, and by Argelander, Schönfeld, and Krüger from 1859.

Bart Bok (Dutch, 1906–1983, Fig. 4.59) pioneered the study of interstellar matter and the structure of our Milky Way galaxy.

4.6.4 Cosmology

Several creators discovered and analyzed dark matter, a mysterious, invisible substance that only interacts with other things via gravity and that surrounds normal matter such as galaxies (Fig. 4.60):

- Jacobus Kapteyn (Dutch, 1851–1922) developed astrophotography, measured galactic rotation rates, and used that data to deduce the existence of dark matter.
- Fritz Zwicky (Swiss, 1898–1974) conducted experimental observations and theoretical analyses of dark matter and stellar physics, and also helped to develop jets and rockets in the United States [John Johnson, Jr., 2019; Stöckli and Müller 2008].
- Jan Oort (Dutch, 1900–1992) studied dark matter and the structure of the Milky Way galaxy, and also proposed the existence of the Oort cloud of comets in the outer reaches of our solar system.

Albert Einstein (German, 1879–1955) predicted the possible existence of dark energy (which he called the cosmological constant) in 1917 [Pais 1982]. As shown in Fig. 4.61, dark energy currently appears to make up approximately 68% of the universe and acts as an antigravitational force to push the universe apart. Approximately 27% of the universe seems to be dark matter, and only about 5% of the universe is atoms or other ordinary matter.

In 1917, Einstein and Willem de Sitter (Dutch, 1872–1934) showed that Einstein's equations of general relativity predicted that the universe should be expanding (or possibly contracting).

In a series of 1918–1924 publications (p. 882), Carl Wilhelm Wirtz (German, 1876–1939) measured the distances and velocities (based on the red-shifting of light) of other galaxies. He demonstrated that the universe was indeed expanding, and that more distant galaxies were moving away from us faster than galaxies closer to us, in agreement with Einstein's and de Sitter's predictions [Wirtz 1918, 1922a, 1922b, 1924, 1936].

Chapter 5

Creators and Creations in Physics and Mathematics

Nicht die Wahrheit, in deren Besitz irgendein Mensch ist oder zu sein vermeinet, sondern die aufrichtige Mühe, die er angewandt hat, hinter die Wahrheit zu kommen, macht den Wert des Menschen. Denn nicht durch den Besitz, sondern durch die Nachforschung der Wahrheit erweitern sich seine Kräfte, worin allein seine immer wachsende Vollkommenheit bestehet.

The true value of a man is not determined by his possession, supposed or real, of Truth, but rather by his sincere exertion to get to the Truth. It is not possession of the Truth, but rather the pursuit of Truth by which he extends his powers and in which his ever-growing perfectibility is to be found.

Gotthold Lessing. 1777. Über die Wahrheit [About the Truth].

This chapter gives an overview of some physics and applied mathematics innovations that have played major roles in the modern world and that were invented or discovered by scientists and engineers who were trained in the predominantly German-speaking central European research world in the nineteenth and early twentieth centuries.

By the mid- to late-nineteenth century, intellectual leadership in applied mathematics and physics research had passed from primarily French and British scientists to German-speaking scientists:[1]

- Prior to that time, many giants of mathematical physics came out of the French intellectual tradition: Pierre-Simon Laplace (1749–1827), Joseph Fourier (1768–1830), André-Marie Ampère (1775–1836), Claude-Louis Navier (1785–1836), Sadi Carnot (1796–1832), and others. However, their numbers declined after that time, perhaps due to the nearly a century of continual political upheaval that followed the French Revolution.
- Several scientists from the United Kingdom made major physics contributions both before this point in time [e.g., Michael Faraday (1791–1867), James Clerk Maxwell (1831–1879), etc.] and after it [e.g., William Henry Bragg (1862–1942), William Lawrence Bragg (1890–1971), Ernest Rutherford (1871–1937), Paul Dirac (1902–1984), etc.]. Nonetheless, their relatively small numbers were soon dwarfed by the large numbers of talented German-speaking physicists.

As covered in this chapter, creators from the German-speaking world made major contributions to:

5.1. Applied mathematics and classical mechanics

5.2. Electromagnetism

5.3. Special and general relativity

5.4. Non-relativistic quantum physics

5.5. Statistical and thermal physics

5.6. Relativistic quantum physics

Scientists from the German-speaking world also made numerous contributions to other physics-related areas listed in Chapters 6 (applied electromagnetic technologies), 8 (nuclear physics), and 9 (applied physics in aerodynamics and spaceflight).

---

[1] In addition to specific references that are cited in different areas throughout this chapter, this chapter makes use of general biographical and project information from: ACLS 2000; Albrecht et al. 1992; Ash and Söllner 1996; Bar-Zohar 1967; Bower 1987; Bunch and Hellemans 2004; Challoner 2009; Cornwell 2003; Crim 2018; EB 1911, 2010; Gillispie 1970–1990; Gimbel 1990a; Glatt 1994; Hall 2019a; István Hargittai 2006, 2011; Linda Hunt 1991; Impey et al. 2008; Jacobsen 2014; Koertge 2007; Kurowski 1982; Lasby 1971; Lusar 1956, 1971; Medawar and Pyke 2000; Mick 2000; Murray 2003; Nachmansohn 1979; NDB 1953–2020; Neufeld 2012; Nouzille and Huwart 1999; O'Reagan 2014, 2019; Porter 1994; Charles Walker 1946; Peter Watson 2010; Weitensfelder 2009.

For general overviews of large portions of the history of physics in the German-speaking world, see: Laurie Brown et al. 1995; István Hargittai 2002, 2006, 2011; Jungnickel and McCormmach 1986, 2017; Kragh 2002; von Meÿenn 1997; Teichmann 2008; Weber 1988.

I have deliberately left a blank space where images of some creators or creations should go. Those are people or projects that I felt were important enough that they should definitely be shown in this book, yet I have not yet been able to locate a suitable image that I have permission to use, despite my searches in Europe and in the United States. If readers have any relevant images and could send them to me, I would be very grateful and will include them in future editions of this book. Even where a suitable photo cannot be located, I believe that leaving a blank space pays tribute both to the scientific importance of that creator or creation and to how that historical fact has been very nearly forgotten.

5.1 Applied Mathematics and Classical Mechanics

Beginning in the nineteenth century, applied mathematics and classical mechanics were dominated by a long list of creators from the German speaking world, as shown by the examples in this section. Today, mathematicians, physicists, and engineers still use Bessel functions, Christoffel symbols, Jacobians, Kronecker delta functions, Noether's theorem, Riemannian geometry, and other contributions made by those scientists and mathematicians. Even children learn about Möbius strips and Klein bottles, and university students still learn from the two-volume mathematical textbook of Courant and Hilbert.

5.1.1 Creators and Creations Before 1800

Although the German-speaking mathematics and physics research world became more established after 1800, there were some very important earlier creators in applied math and physics that must be mentioned.

Nicolaus Copernicus (Prussian, 1473–1543, p. 786) proposed that the planets orbit around the sun and conducted other research in physics and math.

Tycho Brahe (Danish but educated and worked in the German-speaking world, 1546–1601, p. 787) made detailed astronomical observations that were used by Johannes Kepler to calculate planetary orbits.

Johannes Kepler (Weil der Stadt, 1571–1630, p. 788) worked out the physics of planetary orbits and also did other work in physics and math.

Otto von Guericke (also spelled von Gericke; German states, 1602–1686, p. 1488) established the physics of water and air pressure, and also studied the electrostatic force and other forces. He used those discoveries to create several ingenuous inventions [Harsch 2007b].

Christiaan Huygens (Dutch, 1629–1695, Fig. 5.1) derived mathematical formulas describing centripetal force, pendulums, optics, and other important aspects of mathematics and classical mechanics [Andriesse 2005].

Gottfried Leibniz (Saxony, 1646–1716, Fig. 5.1) developed differential and integral calculus and made numerous other contributions to mathematics and classical mechanics (including the conservation of energy and the idea that time and space could be relative instead of absolute). Leibniz also developed binary mathematics and built calculating machines (p. 1160). He designed other hardware from mining equipment to prototype submarines and proposed very prescient theories regarding everything from biological evolution to the interior structure of the Earth [Antognazza 2009].

Daniel Bernoulli (Swiss, 1700–1782, p. 1659) derived the Bernoulli equation for incompressible, inviscid fluid flow, and published it in 1738. He also made important contributions to the theory of flexible beams, probability, statistics, and economic theory.

Leonhard Euler (Swiss, 1707–1783, Fig. 5.1) made extensive contributions to calculus, complex number theory, topology and graph theory, mechanical stress and strain calculations, astronomy, optics, fluid mechanics, logic, and other topics [Calinger 2015; Richeson 2008].

Applied mathematics and classical mechanics
Christiaan Huygens (1629–1695)
Gottfried Leibniz (1646–1716)
Leonhard Euler (1707–1783)

5.1.2 Creators and Creations After 1800

From around 1800 onward, the number and importance of people in the greater German-speaking world who made major contributions to mathematics and classical mechanics steadily increased until they dominated these fields.[2] In fact, the number of contributors was so great that this section will only briefly list some of the more notable ones (shown in Figs. 5.2–5.17) and their accomplishments in alphabetical order.

Emil Artin (Austrian, 1898–1962) made major contributions in algebraic number theory, class field theory, and other areas of mathematics, and is also remembered for his Artin's conjectures on certain mathematical problems.

Stefan Banach (Polish, 1892–1945) developed the general theory of functional analysis and introduced many mathematical concepts that still bear his name, such as Banach algebras, the Banach fixed-point theorem, Banach measures, Banach space, the Banach-Alaoglu theorem, the Banach-Mazur game, the Banach-Steinhaus theorem, the Banach-Tarski paradox, the Hahn-Banach theorem, etc.

Paul Bernays (Swiss, 1888–1977) made important discoveries in axiomatic set theory, mathematical logic, and complex analysis. He worked closely with David Hilbert, for example on what is now known as the Hilbert-Bernays paradox.

In addition to fundamental discoveries in astronomy, Friedrich Bessel (Minden, 1784–1846) made major contributions to applied mathematics, which he used to analyze his astronomical data. In particular, he developed what are now called Bessel functions, which are especially useful for describing waves (such as electromagnetic waves, sound waves, or quantum waves) in cylindrical geometries like pipes and waveguides.

János Bolyai (Hungarian, 1802–1860) helped to develop non-Euclidean geometry, or mathematics describing dimensions that are warped, such as Albert Einstein later used in analyzing how gravity warps the dimensions of space and time. He was the son of Wolfgang Farkas Bolyai.

Wolfgang Farkas Bolyai (Hungarian, 1775–1856) did important work on new methods of analysis in geometry and on iterative and convergent solutions to mathematical problems. He was the father of János Bolyai.

Bernardus Bolzano (Bohemian, 1781–1848) contributed in the areas of math analysis, analytic proofs, and mathematical limits, and his name is remembered in theorems such as Bolzano's theorem and the Bolzano-Weierstrass theorem.

Alexander von Brill (German, 1842–1935) worked in the area of algebraic geometry and functions, and is perhaps best remembered for Brill-Noether theory. One of his students was Max Planck, who went on to help found the field of quantum physics (p. 890).

---

[2] For good overviews of this area, see especially: Grattan-Guinness 1998; Jungnickel and McCormmach 1986, 2017; Kragh 2002. On the end of this era, see Segal 2003. For a much more extensive list, with excellent details about each mathematician, see: https://mathshistory.st-andrews.ac.uk/Countries/.

Luitzen Brouwer (Dutch, 1881–1966) did important work in complex analysis, measure theory, set theory, and topology. His name is still attached to concepts such as the Brouwer fixed-point theorem and the Phragmen-Brouwer theorem.

Karl Hermann Brunn (German, 1862–1939) conducted research in convex geometry and knot theory. He is known for Brunnian links and the Brunn-Minkowski inequality.

Heinrich Burkhardt (German, 1861–1914) worked on Fourier analysis, real-variable analysis, and group theory.

Georg Cantor (born in Russia but educated and worked in Germany, 1845–1918) developed the theory of mathematical sets and applied it to a wide range of cases, greatly influencing later mathematicians such as John von Neumann. He also made major contributions to Fourier analysis and the foundations of real analysis.

Constantin Carathéodory (German, 1873–1950) made important findings regarding the calculus of variations, conformal representations, measure theory, and real analysis.

Elwin Christoffel (German, 1829–1900) worked in complex variable analysis, differential geometry, number analysis, and Abelian functions and integrals. He is best remembered for creating certain tensors or matrices that are now called Christoffel symbols, which describe warped dimensions and were later incorporated into the theory of general relativity by Albert Einstein.

Rudolf Alfred Clebsch (German, 1833–1872) made useful discoveries in algebraic geometry and invariant theory. His name is still remembered in Clebsch surfaces, Clebsch representations and Clebsch potentials, and (with Paul Gordan) the Clebsch-Gordon coefficients that physicists later found useful for describing the quantum behavior of electron clouds in atoms.

Lothar Collatz (German, 1910–1990) specialized in developing novel numerical methods for finding approximate solutions to difficult equations. Among other creations, he is remembered for the Collatz conjecture and the Collatz-Wielandt formula.

Richard Courant (German, 1888–1972) made a wide range of contributions to mathematics during his long career. In modern times, he is especially remembered for developing finite element methods to produce approximate numerical solutions of differential equations to any desired accuracy, which became especially useful once computers were available. In collaboration with David Hilbert, he wrote a two-volume textbook, *Methods of Mathematical Physics*, that is still widely used in university courses today.

Richard Dedekind (German, 1831–1916) did important work in abstract algebra, algebraic number theory, the axiomatic foundation for the natural numbers, real numbers, and other areas of mathematics. He was the last doctoral student of Carl Friedrich Gauss.

Max Dehn (German, 1878–1952) made useful innovations in geometry, group theory, and topology, and his name is attached to concepts such as Dehn's algorithm, Dehn functions, and the Dehn-Nielsen theorem.

Peter Gustav Lejeune Dirichlet (Prussian, 1805–1859) made so many vital contributions to mathematics, especially in the areas of number theory, Fourier series, and mathematical analysis, that his name remains attached to well over two dozen different mathematical concepts that are still in use. Those mathematical innovations named after him include: Dirichlet's approximation theorem, the Dirichlet beta function, Dirichlet boundary conditions, Dirichlet's box principle, Dirichlet characters, Dirichlet conditions, Dirichlet convolution, the Dirichlet density, Dirichlet distributions of several types, the Dirichlet divisor problem, the Dirichlet eigenvalue, Dirichlet's ellipsoidal function, Dirichlet's energy, the Dirichlet form, the Dirichlet function, Dirichlet integrals, Dirichlet kernels, the Dirichlet L-function, the Dirichlet principle, the Dirichlet problem, Dirichlet processes of different types, the Dirichlet ring, Dirichlet series, Dirichlet space, the Dirichlet stability criterion, Dirichlet tessellation or cells, Dirichlet's test, Dirichlet's theorem on arithmetic progressions, and Dirichlet's unit theorem.

Paul du Bois Reymond (German, 1831–1889) worked in the areas of differential equations, Fourier analysis, and real-variable analysis.

Walther von Dyck (German, 1856–1934) made many contributions to group theory and Riemann surfaces. His name remains attached to Dyck graphs, Dyck groups, Dyck language, Dyck paths, Dyck's surface, Dyck tessellations, and Dyck's theorem.

Samuel Eilenberg (Polish, 1913–1998) worked in algebraic topology and automata theory, developed category theory, and is remembered for mathematical constructs such as the Eilenberg swindle and the Eilenberg-Steenrod axioms.

Andreas von Ettingshausen (Austrian, 1796–1878) made important contributions to combinatorial analysis that are widely used in probability and physics, and also conducted extensive research in electromagnetism and optics.

Alfred Enneper (German, 1830–1885) worked in several areas of mathematics and is especially remembered for Enneper's minimal surfaces and Enneper-Weierstrass parameterization.

Erwin Fehlberg (German, 1911–1990) developed improved numerical methods for finding approximate solutions to differential equations, most notably the Runge-Kutta-Fehlberg method. Fehlberg moved to the United States after World War II and was ultimately awarded NASA's Exceptional Scientific Achievement Medal for his work calculating trajectories for the Apollo missions to the moon.

William Feller (Austro-Hungarian Croatian, 1906–1970) did most of his work in probability and statistics, but also contributed to mathematical analysis, geometry, and other areas. His name is attached to Feller's explosion test, Feller-Brown movement, Feller processes, and the Lindeberg-Feller theorem.

Abraham Fränkel (German, 1891–1965) worked in axiomatic set theory; his name is still remembered in the Zermelo-Fränkel axioms.

Friedrich Gottlob Frege (German, 1848–1925) focused on the field of mathematical logic; his name is tied to the Frege-Church ontology, the Frege-Geach problem, Frege's puzzles, the Frege-Russell view, and Frege's theorem.

Robert Fricke (German, 1861–1930) worked in the areas of automorphic functions and elliptic functions. He is perhaps best remembered for Fricke involution and for his collaborative writings with Felix Klein.

Georg Frobenius (German, 1849–1917) made many contributions to differential equations, elliptic functions, group theory, and number theory. His name is attached to concepts such as Frobenius manifolds, the Frobenius matrix, the Frobenius method, and the Frobenius-Stickelberger formulae.

Lazarus Immanuel Fuchs (German, 1833–1902) made important innovations in complex variable analysis and Abelian functions and integrals. He focused especially on methods of solving differential equations, and is remembered for Fuchs's conditions, Fuchsian groups, Fuchs's theorem, and the Picard-Fuchs equation. He was the father of Maximilian Fuchs.

Maximilian Ernst Richard Fuchs (German, 1873–1944), the son of Lazarus Fuchs, continued and significantly extended his father's work on differential equations.

Karl Rudolf Fueter (Swiss, 1880–1950) worked on algebraic number theory and quaternions, and is known for the Fueter-Pólya theorem.

Carl Friedrich Gauss (German states, 1777–1855) made discoveries in mathematics, science, and engineering that were staggering in both their number and importance [Dunnington 1955]. Among other mathematical accomplishments, he proved several important theorems in algebra, was the first to consider non-Euclidean geometries, and discovered four-dimensional complex numbers (quaternions) in 1819. (See also pp. 740, 793, 858, and 972.)

Kurt Gödel (Austrian, 1906–1978) made revolutionary contributions to mathematical logic and set theory. His name is immortalized with Gödel's incompleteness and completeness theorems, the Gödel metric, Gödel numbering, the Gödel ontological proof, and Gödel-Dummett logic.

Paul Gordan (German, 1837–1912) made many contributions to invariant theory as well as Abelian functions and integrals, developed the Clebsch-Gordan coefficients with Rudolf Clebsch, and is also known for Gordan's lemma. He was the doctoral advisor of Emmy Noether.

Hermann Grassmann (German, 1809–1877) developed a whole field that is now known as Grassmann algebra; it combines algebra, geometry, and group theory in an approach that is useful for solving a wide variety of problems.

Hermann Hankel (German, 1839–1873) worked in complex analysis and other areas of mathematics. He is especially remembered for the Hankel contour, Hankel functions, the Hankel matrix, and the Hankel transform.

Carl Gustav Axel Harnack (Baltic German, 1851–1888) made contributions in the areas of real-variable analysis and also algebraic geometry and functions. He is still remembered for Harnack's inequality, Harnack's principle, and Harnack's theorem.

Friedrich Hartogs (German, 1874–1943) developed many important concepts in set theory and complex analysis, such as the Hartogs domain, Hartogs's extension theorem, Hartogs's function, Hartogs's lemma, the Hartogs number, Hartogs's theorem, the Hartogs-Laurent expansion, and the Hartogs-Rosenthal theorem.

Felix Hausdorff (German, 1868–1942) made major contributions in topology, set theory, measure theory, and functional analysis. He is known for the Hausdorff dimension, Hausdorff distance, the Hausdorff maximal principle, the Hausdorff measure, the Hausdorff moment problem, the Hausdorff paradox, Hausdorff space, and the Hausdorff-Young inequality.

Heinrich Eduard Heine (German, 1821–1881, not to be confused with the earlier German poet Heinrich Heine) worked in real analysis and introduced important innovations regarding spherical harmonics, Legendre functions, hypergeometric series, and other mathematical approaches. His name remains known via the Heine-Borel theorem, the Heine-Cantor theorem, Heine-Stieltjes polynomials, the Heine definition of continuity, Heine functions, Heine's identity, and the Mehler-Heine formula.

David Hilbert (German, 1862–1943) made huge contributions to many areas of mathematics, including algebraic number theory, the calculus of variations, commutative algebra, Euclidean and non-Euclidean geometry, and invariant theory. His name remains associated with Hilbert's axioms, Hilbert's basis theorem, Hilbert's problems, Hilbert's program, and Hilbert space. In collaboration with Richard Courant, he wrote a two-volume textbook, *Methods of Mathematical Physics*, that is still widely used.

Heinz Hopf (German, 1894–1971) worked in topology and geometry, and is known for many concepts, such as Hopf algebra, the Hopf conjecture, Hopf fibration, the Hopf invariant, the Hopf link, the Hopf manifold, the Hopf map, Hopf surfaces, the Hopf theorem, and the Killing-Hopf theorem.

Adolf Hurwitz (German, 1859–1919) contributed to complex variable analysis, elliptic functions, real-variable analysis, and Riemann surfaces. He is remembered for Hurwitz's automorphisms theorem, Hurwitz quaternions, the Riemann-Hurwitz formula, and the Routh-Hurwitz stability criterion.

Carl Gustav Jacobi (Prussian, 1804–1851) introduced important innovations in the classical mechanics of orbits, differential equations, elliptic functions, and number theory. His name is widely recognized from concepts such as the Jacobian, the Jacobi ellipsoid, Jacobi's elliptic functions, the Jacobi identity, the Jacobi method, Jacobi operators, Jacobi polynomials, Jacobi symbols, the Jacobi transform, and the Hamilton-Jacobi equation.

Theodor Kaluza (German, 1885–1954) produced very creative ideas regarding non-Euclidean geometries and extra dimensions that proved useful in some versions of relativity and unified field theories. His son Theodor Kaluza Jr. (German, 1910–1994) was also a mathematician.

Wilhelm Killing (German, 1847–1923) made numerous important contributions to group theory. His name is attached to many concepts, such as the Killing equation, the Killing form, the Killing-Hopf theorem, the Killing horizon, the Killing spinor, the Killing tensor, and the Killing vector field.

Christian Felix Klein (German, 1849–1925) made a large number of discoveries in algebraic geometry and functions, automorphic functions, elliptic functions, and Riemann surfaces. His mathematical innovations found many later applications in theoretical physics. He also created the structure now known as a Klein bottle, somewhat like a three-dimensional Möbius strip.

Sofia Kovalevskaya (Russian but educated in Germany, 1850–1891) did important work in differential equations, as well as Abelian functions and integrals. She is still known from the Cauchy-Kowalevski theorem.

Leopold Kronecker (German, 1823–1891) made research advances in algebra, mathematical logic, and number theory. Today is he remembered from the Kronecker delta function, Kronecker's lemma, the Kronecker product, the Kronecker symbol, Kronecker's theorem, and the Kronecker-Weber theorem.

Ernst Kummer (German, 1810–1893) worked on Bessel functions, class field theory, hypergeometric series, and other topics. His name remains linked to Kummer extensions of fields, the Kummer surface, and Kummer theory.

Martin Wilhelm Kutta (German, 1867–1944) developed practical methods of extracting useful answers from very complicated physics and engineering equations, especially in aerodynamics. He collaborated with Carl Runge to create the Runge-Kutta methods of producing approximate but sufficiently accurate numerical solutions to differential equations. He also developed complex analysis transformations for solving the equations for airflow around wings and other objects.

Daniel Christian Ludolph Lehmus (German, 1780–1863) worked in geometry and is especially remembered for the Steiner-Lehmus theorem.

Sophus Lie (Norwegian but studied and worked in Germany, 1842–1899) made huge contributions to differential equations and group theory that are now widely used in theoretical physics. His name is immortalized in concepts such as Lie algebra, Lie groups, Lie symmetries, and Lie theorems.

Carl Ferdinand von Lindemann (German, 1852–1939) worked in algebraic geometry and functions, and became famous for proving that π is a transcendental number. He was also the doctoral advisor for prominent mathematicians and physicists such as David Hilbert, Martin Kutta, Alfred Loewy, Hermann Minkowski, Oskar Perron, Arthur Rosenthal, and Arnold Sommerfeld.

Rudolf Lipschitz (German, 1832–1903) made important contributions to differential equations, real-variable analysis, and Fourier analysis. Perhaps most importantly, he independently discovered "Clifford algebras" at approximately the same time or earlier than William Clifford (English, 1845–1879), but with far less fame. He is remembered with the Lipschitz continuity condition, the Lipschitz integral condition, and the Lipschitz quaternion.

Alfred Loewy (German, 1873–1935) focused on representation theory and introduced innovations now known as Loewy decomposition, the Loewy length, Loewy rings, and Loewy series.

Gustav Ferdinand Mehler (German, 1835–1895) worked in several areas of mathematics, and is noted for Mehler's formula, Mehler functions, the Mehler kernel, the Mehler-Fock transform, and the Mehler-Heine formula.

Friedrich Wilhelm Franz Meyer (German, 1856–1934) spent his career investigating algebraic geometry and functions.

Hermann Minkowski (German, 1864–1909) did important work in geometry and number theory, and also contributed to the development of the theory of relativity. His name is still attached to concepts such as Minkowski addition, Minkowski content, Minkowski diagrams, Minkowski's question mark function, Minkowski space, the Minkowski functional, the Minkowski inequality, the Minkowski problem, Minkowski's bound, Minkowski's theorem in geometry of numbers, and the Brunn-Minkowski inequality.

Richard von Mises (Austro-Hungarian, 1883–1953) developed mathematical methods of solving equations in aerodynamics and the mechanics of materials, working with differential equations, complex analysis, probability, and statistics.

August Möbius (Saxony, 1790–1868) worked in topology and geometry as well as astronomy. He is particularly famous for the Möbius strip (a figure-8 formed from a strip of paper, which effectively only has one side), but he is also known for the Möbius function, the Möbius inversion formula, Möbius transformations, the Möbius-Kantor configuration, and the Möbius-Kantor graph.

Carl Neumann (German, 1832–1925), the son of physicist Franz Ernst Neumann, developed mathematical methods for analyzing physics problems. He is especially remembered for the Neumann boundary condition and Neumann series.

John von Neumann (Hungarian, 1903–1957) contributed a vast number of innovations to mathematics, physics, engineering, computer science, and economics [Macrae 1992]. Among many other contributions, he is known for von Neumann algebra, von Neumann architecture, the von Neumann bicommutant theorem, the von Neumann cardinal assignment, the von Neumann cellular automaton, the von Neumann conjecture, the von Neumann entropy, the von Neumann equation, the von Neumann ergodic theorem, the von Neumann extractor, von Neumann's inequality, von Neumann interpretation, the von Neumann measurement scheme, the von Neumann neighborhood, von Neumann ordinals, the von Neumann paradox, the von Neumann regular ring, the von Neumann spectral theorem, von Neumann stability analysis, the von Neumann universal constructor, the von Neumann universe, and von Neumann-Bernays-Gödel set theory.

Rolf Nevanlinna (Finnish but an active part of the German research world, 1895–1980) worked in complex analysis and developed what are now known as Nevanlinna theory and Nevanlinna class functions.

Emmy Noether (German, 1882–1935), the daughter of Max Noether, made revolutionary discoveries in both mathematics and theoretical physics. In mathematics, she worked on algebraic invariants, number fields, abstract algebra, noncommutative algebras, hypercomplex numbers, group theory, and topology. In physics, she is most famous for discovering Noether's theorem, which explains the relationship between conservation laws (such as the conservation of energy or the conservation of momentum) and symmetries (ways that variables such as time and space can be shifted without altering the fundamental laws of physics). Noether's theorem has been employed in many areas of physics since she first articulated it.

Max Noether (German, 1844–1921) conducted research on algebraic functions, algebraic geometry, and Riemann surfaces. His full name (to distinguish him from his even more famous daughter) is attached to Max Noether's inequality, Max Noether's residual intersection theorem, Max Noether's theorem on canonical curves, Max Noether's theorem on the Cremona group, Max Noether's theorem on curves on algebraic surfaces, and Max Noether's theorem on rationality for surfaces.

Moritz Pasch (German, 1843–1930) focused on algebraic geometry and functions and the foundations of geometry. He is most noted for Pasch's axiom.

Oskar Perron (German, 1880–1975) worked on differential equations and continued fractions, and is known for the Perron method for solving elliptic differential equations and for Perron's paradox.

Ernst Peschl (German, 1906–1986) made important contributions to complex analysis, the solution of partial differential equations, and differential geometry.

Michel Plancherel (Swiss, 1885–1967) worked in mathematical analysis and algebra, and is remembered for the Plancherel measure, the Plancherel theorem for harmonic analysis, and the Plancherel theorem for spherical functions.

Julius Plücker (German states, 1801–1868) contributed to geometry and also physics. In mathematics, he is known for Plücker's conoid, Plücker coordinates, Plücker embedding, the Plücker formula, the Plücker matrix, the Plücker relations, and the Plücker surface.

George Pólya (Hungarian, 1887–1985) worked in many areas of mathematics, including algebra, combinatorics, geometry, mathematical analysis, number theory, probability, and series. He is associated with numerous concepts such as the Pólya-Aeppli distribution, the Pólya conjecture, the Pólya distribution, the Pólya enumeration theorem, the Pólya inequality, the Pólya urn model, the Fueter-Pólya theorem, and the Hilbert-Pólya conjecture.

Alfred Pringsheim (German, 1850–1941) contributed to real-variable analysis, the foundations of real analysis, and Fourier analysis.

Bernhard Riemann (Kingdom of Hanover, 1826–1866) made enormous contributions to differential geometry, mathematical analysis, number theory, and other fields of mathematics. In particular, his methods of using tensors in differential geometry later proved especially useful to describe how gravity warps space and time, as Albert Einstein found. Riemann's name is attached to dozens of concepts, including Riemann bilinear relations, Riemann conditions, Riemann's differential equation, Riemann's existence theorem, Riemann's explicit formula, the Riemann form, the Riemann function, Riemannian geometry, the Riemann-Hurwitz formula, the Riemann hypothesis, the Riemann integral, the Riemann invariant, the Riemann matrix, Riemann's minimal surface, the Riemann operator, the Riemann series theorem, the Riemann singularity theorem, the Riemann sum, the Riemann surface, Riemann's theorem on removable singularities, the Riemann theta function, the Riemann Xi function, and the Riemann zeta function.

Arthur Rosenthal (German, 1887–1959) worked in geometry, mathematical analysis, and dynamical systems analysis. He is perhaps best known for the Hartogs-Rosenthal theorem.

Carl Runge (German, 1856–1927) made important contributions to numerical analysis and spectroscopy. He collaborated with Martin Wilhelm Kutta to develop the Runge-Kutta methods of numerically solving differential equations. He is also known for Runge's phenomenon, the behavior of certain errors that occur when finding approximate answers for functions. Carl Runge's son, Wilhelm Runge, was one of the developers of radar (p. 1220).

Ludwig Schlesinger (German, 1864–1933) conducted research in the areas of automorphic functions and differential equations. His name remain attached to the Schlesinger equations and Schlesinger transformations.

Arthur Schönflies (German, 1853–1928) made major contributions to group theory, set theory, and topology. His name is still widely known from Schönflies notation, Schönflies displacement, and Schönflies problems.

Friedrich Schottky (German, 1851–1935) worked on Abelian functions and integrals, complex variable analysis, and elliptic functions. He is remembered for the Schottky form, the Schottky-Klein prime form, Schottky groups, the Schottky problem, and Schottky's theorem. He was the father of Walter Schottky, one of the pioneers of semiconductor microelectronics (p. 1050).

Issai Schur (Russian but studied and worked in Germany, 1875–1941) performed innovative research in group theory, number theory, and combinatorics. He is best remembered for Schur decomposition and Schur's lemma.

Karl Hermann Amandus Schwarz (German, 1843–1921) made many contributions to complex variable analysis and differential equations. His name remains well known from concepts such as the additive Schwarz method, the Schwarz alternating method, the Schwarzian derivative, the Schwarz lantern, the Schwarz lemma, Schwarz's list, the Schwarz minimal surface, the Schwarz theorem, the Schwarz integral formula, Schwarz-Christoffel mapping, the Schwarz reflection principle, the Schwarz triangle, and the Cauchy-Schwarz inequality.

Jakob Steiner (Swiss, 1796–1863) carried out work in geometry and other areas of mathematics. He is remembered in names such as the Steinerian, the Steiner chain, Steiner's conic problem, the Steiner inellipse, the Steiner point, Steiner's problem, the Steiner surface, the Steiner system, the Steiner tree, the Steiner-Lehmus theorem, and the Poncelet-Steiner theorem.

Ludwig Stickelberger (Swiss, 1850–1936) made important contributions to linear algebra and number theory, such as the Stickelberger relation and the Frobenius-Stickelberger theorem.

Thomas Joannes Stieltjes (Dutch, 1856–1894) worked in mathematical analysis, continued fractions, and number theory. His name is attached to the Riemann-Stieltjes integral.

Otto Stolz (Austrian, 1842–1905) did innovative research in complex variable analysis and the foundations of real analysis.

Oswald Teichmüller (German, 1913–1943) made important contributions in complex analysis and is best known for Teichmüller space and Teichmüller theory.

B. L. van der Waerden (Dutch, 1903–1996) contributed to abstract algebra and algebraic geometry. He is remembered for concepts such as van der Waerden's conjecture, van der Waerden notation, the van der Waerden number, the van der Waerden test, and van der Waerden's theorem.

Heinrich Martin Weber (German, 1842–1913) did work in algebra, mathematical analysis, and number theory. His name is associated with Weber functions, Weber's theorem, and the Kronecker-Weber theorem.

Karl Weierstrass (German, 1815–1897) made major advances in a wide range of areas, including Abelian functions and integrals, complex variable analysis, elliptic functions, the foundations of real analysis, and real-variable analysis. He is known for concepts such as the Weierstrass approximation theorem, Weierstrass coordinates, Weierstrass's elliptic functions, the Weierstrass equation, the Weierstrass factorization theorem, the Weierstrass function, the Weierstrass M-test, the Weierstrass point, the Weierstrass preparation theorem, the Weierstrass product inequality, the Weierstrass ring, and the Weierstrass transform.

Hermann Weyl (German, 1885–1955) introduced important innovations in group theory, number theory, and non-Euclidean geometry, as well as general relativity. His name remains attached to countless concepts such as Weyl algebra, the Weyl basis of the gamma matrices, the Weyl chamber, the Weyl character formula, the Weyl equation, Weyl fermions, the Weyl gauge, Weyl gravity, Weyl notation, Weyl quantization, Weyl spinors, Weyl sums, Weyl symmetry, Weyl tensors, Weyl transformations, the Weyl-Schouten theorem, Weyl's criterion, and Weyl's lemmas.

Hans Zassenhaus (German, 1912–1991) worked in abstract algebra and group theory, and helped to develop computer algebra and number theory.

Ernst Zermelo (German, 1871–1953) made many contributions to set theory and mathematical logic, such as Zermelo-Fränkel set theory, Zermelo's navigation problem, the Zermelo ordinal, and Zermelo's theorem.

5.2 Electromagnetism

Electromagnetic theory describes the behavior of electric fields, electric currents, magnetic fields, and electromagnetic waves (such as light and radio waves). The German-speaking scientific world slowly ramped up during the nineteenth century, and before then scientists had already begun working out the laws of electromagnetism. Therefore, most of the major early electromagnetic discoveries came from scientists outside the German-speaking world, including:

- Italian scientists (e.g., Luigi Galvani and Alessandro Volta).
- British scientists (e.g., Michael Faraday and James Clerk Maxwell).
- French scientists (e.g., André-Marie Ampère and Charles-Augustin de Coulomb).
- Hans Christian Ørsted in Denmark.
- Benjamin Franklin in the United States.

As the German-speaking scientific world became larger and more advanced over the course of the nineteenth century, German-speaking scientists came to increasingly dominate new discoveries in electromagnetism; see Figs. 5.18–5.23 for some examples.[3] That dominance is reflected in the modern physics terminology of Doppler shifts, Gauss's law, Helmholtz coils, Kirchhoff's laws, Lenz's law, Lorentz force, Ohm's law, and various physics quantities measured in Gauss, Hertz, Ohms, Siemens, Teslas, and Webers.

For convenience, the creators and creations in this section are divided into the following broad (and somewhat overlapping) categories:

5.2.1. Electric currents and magnetic fields

5.2.2. Electromagnetic waves

5.2.3. Electron beams and proton beams

The fundamental physics discoveries in electromagnetism led to a vast range of applications, which is the field of electrical and electromagnetic engineering; see Chapter 6 for more information.

5.2.1 Electric Currents and Magnetic Fields

Carl Friedrich Gauss (German states, 1777–1855) and Wilhelm Weber (German, 1804–1891) conducted magnetic research together, building the first electromagnetic telegraph in 1833 (p. 974) and creating maps based on geomagnetic measurements. Along the way, Gauss discovered what is now known as Gauss's law, which determines how magnetic fields are created and spread out [Dunnington 1955]. (See also pp. 740, 793, 828, and 972.) The cgs (centimeter-gram-second) unit of magnetic field strength is named in Gauss's honor, and the metric SI (Système International) unit of magnetic flux is named after Weber.

Georg Ohm (German states, 1789–1854) studied the electrical properties of circuits and demonstrated that the voltage difference V across an electrical component depends on the current I through the component and the electrical resistance R of the component, in accordance with the equation $V = IR$, which is now known as Ohm's law. (See Fig. 5.18 top.) The unit of electrical resistance is named in his honor.

Andreas von Ettingshausen (Austrian, 1796–1878) designed the first machine to use electromagnetic induction to generate power, and also did research in optics.

Franz Ernst Neumann (German, 1798–1895) worked out laws for the induction of currents by magnetic fields, as well as the optical behavior of crystals.

Heinrich Lenz (Baltic German, 1804–1865) formulated what is now known as Lenz's law, which describes how a changing magnetic field induces electric currents in nearby conductors that create new magnetic fields opposing the changing field. He also discovered that the power P consumed by an electric circuit depends on the current I flowing through the circuit and the electrical resistance R of the circuit, $P = I^2R$.

Heinrich Rühmkorff (German, 1803–1877) developed improved magnetic induction coils, now called Rühmkorff coils, and used them in a variety of applications such as high-voltage generators (p. 949). He also investigated the rotation of the plane of polarized light in magnetic media, thermoelectric effects, and other aspects of electromagnetism.

Werner von Siemens (German, 1816–1892) began his career by creating more sophisticated telegraphs that could point to individual letters, and went on to produce a wide range of additional electrical innovations such as generators and transformers (pp. 950 and 975). The unit of electrical conductivity (the inverse of electrical resistance) is named in his honor [Bähr 2016; von Siemens 1895].

Gustav Kirchhoff (German, 1824–1887) discovered a number of physical laws that now have his name attached to them. Kirchhoff's various laws describe the current and voltage in electric circuits (p. 951), the emission and absorption spectra of materials as measured by spectroscopy (p. 433), and the emission and absorption of thermal radiation (p. 915).

Hendrik Lorentz (Dutch, 1853–1928) made many contributions to electromagnetism and other areas of physics, including formulating what is now called the Lorentz force, the force that electric and magnetic fields exert on a particle with a given electric charge and velocity. He won the Nobel Prize in Physics in 1902 (p. 891).

Johann Christian Poggendorff (German, 1796–1877), Wilhelm Holtz (German, 1836–1913), and August Toepler (German, 1836–1912) each built very early high-voltage generators and used those to study electrostatics. Other physicists used such high-voltage generators to power some of the earliest cathode ray tubes for producing electron beams.

5.2.2 Electromagnetic Waves

Joseph von Fraunhofer (German states, 1787–1826) made a number of important discoveries and inventions in optics. He improved prisms, invented diffraction grating, and studied the diffraction of light of different wavelengths. He used a diffraction slit and prism to develop a spectroscope, which he and others then applied to make important measurements in physics and chemistry (p. 961). He also created achromatic telescope lenses and other specialized lenses. Through all of these developments, von Fraunhofer learned and applied a great deal of knowledge about the behavior of light waves.

Christian Doppler (Austrian, 1803–1853) discovered and explained how the wavelength and frequency of waves changes depending on the velocity of the object emitting the waves, which is now commonly known as the Doppler effect. (See Fig. 5.18 middle.)

In 1856, Wilhelm Weber collaborated with Rudolf Kohlrausch (German states, 1809–1858) to combine the laws governing electric fields with those governing magnetic fields, and to use those to show that light is an electromagnetic wave with its speed c (as Weber and Kohlrausch labelled it) given by those equations. [Rudolf Kohlrausch was the father of Friedrich Kohlrausch (p. 599).] At approximately the same time, Gustav Kirchhoff independently arrived at a mathematical derivation of the speed of electromagnetic waves. Several years later, in the 1860s and 1870s, James Clerk Maxwell (Scottish, 1831–1879) also derived and published the equations for electromagnetic waves and the speed of light. In his published papers, Maxwell specifically gave credit to Weber's earlier work. It could be interesting for historians to more closely scrutinize the connections, similarities, and differences between Maxwell's work and the earlier work by Weber, Kohlrausch, and Kirchhoff.

Hermann von Helmholtz (German, 1821–1894) made a wide variety of major discoveries in biology (pp. 239, 282, 297, 311), chemistry (p. 597), and physics (p. 912) [Cahan 2018]. In electromagnetic theory, he is best remembered for the Helmholtz equation for electromagnetic waves, and also for Helmholtz electromagnetic coils for producing a very uniform magnetic field within a small volume.

Heinrich Hertz (German, 1857–1894), a student of Gustav Kirchhoff and Hermann von Helmholtz, produced, detected, and measured electromagnetic waves, specifically radio waves, making him also the true original inventor of radio transmitters and receivers. (See Fig. 5.18 bottom.) Unfortunately Hertz died very young; otherwise he would likely have played even more of a role (and been recognized far more) in the early development of radio technology. The unit of frequency (1 Hertz = 1 Hz = 1 wave/second) is named in his honor. Because Hertz died before Nobel Prizes were awarded, he was not eligible to be considered for one. However, Professor Hj. Théel, President of the Royal Swedish Academy of Sciences, paid tribute to Hertz's groundbreaking contributions in his speech for the 1902 Nobel Prize in Physics [https://www.nobelprize.org/prizes/physics/1902/ceremony-speech/]:

> This so-called electromagnetic theory of light of Maxwell's at first aroused compara-

> tively little interest. Twenty years after its first appearance however it led to a scientific discovery which demonstrated its great significance in no uncertain manner. The German physicist Heinrich Hertz then succeeded in demonstrating that the electrical vibrations—which are generated under certain conditions when an electrically charged body is discharged—are propagated through the surrounding space in the form of a wave motion, and that the wave motion spreads at the speed of light and also possesses its properties. This gave a firm experimental basis for the electromagnetic theory of light.

Building on the earlier work of Weber, Kohlrausch, Helmholtz, and Hertz on electromagnetic waves, Ernst Lecher (Austrian, 1856–1926) developed a device that used parallel wires (now called Lecher lines) to measure the wavelength of radio waves.

Nikola Tesla (Serbo-Croatian, educated in Austria, 1856–1943) showed that Hertz's radio waves could be used to transmit signals and even power (using what are now known as Tesla coils) over considerable distances. Tesla also made countless other contributions to electromagnetism and electrical engineering, especially in AC (alternating current) electricity generation, distribution, and usage (p. 954) [Cheney 1981; Cheney and Uth 1999; Tesla 1893, 1904, 1919, 1940]. The SI unit of magnetic field strength is named in his honor.

Although Albert Michelson (1852–1931) was a U.S. citizen, he was born in Prussia, was raised by German-speaking parents, and studied in Berlin and Heidelberg. He developed methods to measure the speed of light very accurately, and then used those methods to demonstrate that the speed of light was the same in all directions. That result showed that light is simply electromagnetic waves in empty space and not waves in some invisible vibrating "ether" material that fills the universe and moves in a particular direction with some velocity relative to the earth. For these experiments, Michelson won the Nobel Prize in Physics in 1907. Professor the Count K. A. H. Mörner, President of the Royal Swedish Academy of Sciences, announced the award [https://www.nobelprize.org/prizes/physics/1907/ceremony-speech/]:

> Professor Michelson. The Swedish Academy of Sciences has awarded you this year the Nobel Prize in Physics in recognition of the methods which you have discovered for insuring exactness in measurements, and also of the investigations in spectrology which you have carried out in connection therewith.
>
> Your interferometer has rendered it possible to obtain a non-material standard of length, possessed of a degree of accuracy never hitherto attained. By its means we are enabled to ensure that the prototype of the metre has remained unaltered in length, and to restore it with absolute infallibility, supposing it were to get lost.
>
> Your contributions to spectrology embrace methods for the determination of the length of waves in a more exact manner than those hitherto known.
>
> Furthermore, you have discovered the important fact that the lines in the spectra, which had been regarded as perfectly distinct, are really in most cases groups of lines. You have also afforded us the means of closely investigating this phenomenon, both in its spontaneous occurrence and when it is produced by magnetic influence, as in Zeeman's interesting experiments.

> Astronomy has also derived great advantage, and will do so yet more in the future, from your method of measurements.

Paul Drude (German, 1863–1906) used the latest ideas about electromagnetic waves and electrons to create some of the first mathematical models for the electrical and optical properties of solids.

Gustav Mie (German, 1868–1957) derived equations for the scattering of electromagnetic waves by spherical particles, which is now called Mie scattering. Mie scattering has proven useful for everything from studying the propagation of light though the atmosphere to designing modern metamaterials. He also analyzed the electrostatic forces between molecules, now called the Mie potential, and made other contributions to electromagnetic theory.

Creators from the German-speaking world also developed a wide range of practical applications of electromagnetic waves, such as:

- Lighting technology (p. 957).
- Radio communications (p. 978).
- Television communications (p. 996).
- Lasers and holography (p. 1023).
- Infrared vision and targeting (p. 1131).
- Radio-controlled robotic vehicles (p. 1198).
- Radar (p. 1217).
- Optical technologies (p. 1260).

5.2.3 Electron, Proton, and Neutron Beams

German-speaking scientists discovered, analyzed, and harnessed electron beams (cathode rays), proton beams (anode rays or canal rays), and neutron beams, thus identifying all three building blocks of the atom.

Heinrich Geissler (German, 1814–1879) invented the first high-voltage, low-pressure gas-filled glass electrical discharge tubes, which other German-speaking creators later adapted for a wide variety of applications ranging from fluorescent lights to television screens.

In the late 1850s and 1860s, Julius Plücker (German states, 1801–1868) and Johann Wilhelm Hittorf (German, 1824–1914) modified Geissler's tubes to produce cathode rays, which were later found to be electron beams, and to measure their properties.

Philipp Lenard (Austrian/German, 1862–1947) conducted a variety of novel experiments with cathode rays beginning in 1888. He demonstrated that the electrons were particles, and he experimentally measured many of their properties. For this work, he won the Nobel Prize in Physics in 1905. Professor A. Lindstedt, President of the Royal Swedish Academy of Sciences, described Lenard's experiments [https://www.nobelprize.org/prizes/physics/1905/ceremony-speech/]:

> The discovery of the cathode rays forms the first link in the chain of brilliant discoveries with which the names of Röntgen, Becquerel and Curie are connected. The discovery itself was made by Hittorf as long ago as 1869 and therefore falls in a period before that which the Nobel Foundation is able to take into account. However, the recognition which Lenard has earned himself by the further development of Hittorf's discovery (which is becoming of increasing importance) shows that he too deserves the same reward as has already come to several of his successors for work of a similar nature. [...]
>
> These were the circumstances prevailing when Lenard began his work on cathode rays in 1893. He started from a fact which had been observed by his great and prematurely deceased teacher Heinrich Hertz: that these rays were able to pass through thin metal plates which had been introduced into the discharge tube. At Hertz's suggestion he utilized this fact in an attempt to lead the rays out of the tube. He used for this a tube which was not wholly made of glass but terminated at one place in a very thin aluminium plate. As the cathode rays reached Lenard's "aluminium window", it was found that they passed through it and continued their course in the air outside the tube. This constituted a discovery which was to have the most far-reaching consequences, above all for the study of the radiation phenomena themselves. It became possible to study cathode rays under much simpler and more convenient experimental conditions than before, and also to separate observations on conditions needed for the production of the rays in the tube from questions concerning their propagation and other characteristics.
>
> Lenard found first of all that the rays coming through the aluminium window possessed the same characteristics as those previously noted in rays inside the tube, i.e. that they cause fluorescence, can be deflected by a magnet and so on. He further proved that cathode rays have certain chemical effects such as causing impressions on photographic plates, ozonizing air, making gases conducting through so-called ionisation, etc. It was also discovered that these rays pass unimpeded through empty space but that in gases

> they are subject to diffusion which increases with the density of the gas; and, moreover, that bodies in general differ in permeability, as their absorptive power bears a direct relationship to their density. Cathode rays proved to be carriers of negative electricity even in empty space and they could be deflected from their path by both magnetic and electrical fields. Finally, Lenard showed that there are various types of cathode rays, differentiated amongst other things by the fact that they are deflected by magnets, to a greater or lesser extent. He also found that the formation of one or other type of ray is determined by the degree of gas rarification in the discharge tube. [...]
>
> The research by Lenard, only a very brief report of which is given here, has been followed by a series of valuable studies by other scientists as well. Development of the theoretical basis for the theory of electrons has gone hand in hand with the experimental work. The study of electrons, their characteristics and their behaviour in relation to matter has been given a sounder basis through these researches on cathode rays and has been gradually developed into one of the foremost theories of modern physics by Lenard himself and by other workers. This theory is in fact not only important for the explanation of cathode rays and other closely related phenomena—the electron theory with its concepts on the constitution of matter has become of the most fundamental importance for the sciences of electricity and of light and for both the physicist and the chemist.

In 1890, Arthur Schuster (German, 1851–1934) measured the charge-to-mass ratio of electrons and showed that it was remarkably large, so electrons were particles with a very small mass compared to atoms. Schuster was also the first physicist to propose the existence of antimatter particles that would annihilate and produce energy if combined with particles of ordinary matter.

The geophysicist Emil Wiechert (German, 1861–1928) also demonstrated that cathode rays were particles and measured their charge-to-mass ratio.

One could make a very strong case that the fact that electrons are particles was discovered by the qualitative demonstrations of Julius Plücker and Johann Hittorf during the 1850s–1860s, or by the quantitative measurements of Lenard, Schuster, and Wiechert in the late 1880s and early 1890s. Yet traditionally, the credit for the discovery of the electron has been given to J. J. Thomson (British, 1856–1940), who conducted very similar but much more widely publicized experiments significantly later, in 1897. For that work, Thomson received the Nobel Prize in Physics in 1906.

Eugen Goldstein (German, 1850–1930) used similar tubes not only to produce and study cathode rays or electrons, but also to produce and analyze anode rays (also called canal rays), which turned out to be positively charged ions, or atomic nuclei. More specifically, Goldstein's anode rays were protons if he used hydrogen gas in his tubes. Goldstein showed that the anode rays were particles with a positive charge and a mass much larger than that of the electron.

Wilhelm Wien (German, 1864–1928) measured the mass of the anode rays produced from hydrogen gas in 1898 and specifically showed that they had the same mass as a hydrogen atom. For some of his other work (thermal radiation), Wien won the Nobel Prize in Physics in 1911 (p. 916).

Thus one could make a convincing case that the proton was discovered in 1886 by Goldstein, or at the latest was more fully demonstrated in 1898 by Wien. Yet traditionally the credit for the discovery of the proton has been given to Ernest Rutherford (New Zealand/British, 1871–1937) for a series of experiments he conducted decades later, during the period 1917–1919.

The neutron was the last of the three building blocks of the atom to be discovered, and it too was discovered by German-speaking scientists. Carl Auer von Welsbach (Austrian, 1858–1929, p. 966) produced free neutrons and observed their effects on various nuclei no later than 1910 [Auer von Welsbach 1910; Steinhauser et al. 2013]. Walther Bothe (German, 1891–1957, p. 1026) and Herbert Becker (German?, 18??–19??) rediscovered the neutron no later than 1930, when they bombarded beryllium with alpha particles from polonium and showed that in response the beryllium emitted a new type of particles that did not match the characteristics of alpha, beta, or gamma radiation [Bothe and Becker 1930]. James Chadwick repeated the Bothe-Becker experiment in 1932 and was trumpeted in the English-speaking world as the “discoverer” of the neutron while the earlier experimental discoveries of Carl Auer von Welsbach, Walther Bothe, and Herbert Becker were forgotten.

Other creators from the German-speaking world devised a wide range of practical applications of high-voltage gas discharge tubes, such as:

- Fluorescent lights (p. 957).
- Vacuum tubes (p. 978).
- Television picture tubes (p. 996).
- Photomultiplier tubes (p. 1131).
- Electron microscopes (p. 1286).
- X-ray tubes (p. 1505).
- Geiger counters (p. 1518).
- Particle beam sources (p. 1524).
- Electric rocket propulsion (p. 1954).
- Fusion reactions and neutron sources (Section D.9).

5.3 Special and General Relativity

The theory of relativity is thus named because it deals with objects that are moving differently relative to each other, as there is no absolute frame of reference to authoritatively declare what is moving and what is not. Relativistic physics was almost entirely a product of German-speaking creators.

Special relativity (Section 5.3.1) only considers the special case in which the objects move at constant velocities.

General relativity (Section 5.3.2) covers the general case in which the objects' velocities can change, or the objects can accelerate and decelerate.

5.3.1 Special Relativity

Special relativity is valid for the special case in which the objects' relative velocities remain constant, with no acceleration or deceleration. Following that initial assumption to its logical if surprising conclusions, special relativity describes the weird things that happen when something travels nearly as fast as the speed of light (relative to some other observer), including time slowing down, lengths contracting, and not being able to travel faster than light speed no matter how hard something is pushed (Fig. 5.24). These strange effects have all been confirmed in countless experiments. At the fundamental level, these effects are manifestations of the facts that space and time are interrelated, and mass and energy are interrelated.

Relativity is quite possibly unique in how much of the field came from a single person, Albert Einstein (German, 1879–1955, Fig. 5.25).[4] Indeed, Einstein and relativity are probably the most famous creator and creation from the entire German-speaking world. In addition to developing special relativity (1905) and general relativity (1915–1916), Einstein also made major contributions to statistical and thermal physics, non-relativistic quantum physics, and relativistic quantum physics, as covered in the next sections.

Shockingly, the Nobel Committee for Physics was unwilling to give Einstein an award for relativity even years later, since they considered it so counterintuitive and controversial. They did give him a Nobel Prize in 1921, but only for his work on the quantum physics of the photoelectric effect (p. 890).

Although Einstein is justifiably lauded for special relativity, at least six other scientists also made significant contributions to special relativity: Hendrik Lorentz, Woldemar Voigt, Ernst Mach, Hermann Minkowski, Walter Kaufmann, and Alfred Bucherer. Many other scientists from the German-speaking world also made contributions to general relativity. See Figs. 5.26–5.30.

3. *Zur Elektrodynamik bewegter Körper;*
von A. Einstein.

Daß die Elektrodynamik Maxwells — wie dieselbe gegenwärtig aufgefaßt zu werden pflegt — in ihrer Anwendung auf bewegte Körper zu Asymmetrien führt, welche den Phänomenen nicht anzuhaften scheinen, ist bekannt. Man denke z. B. an die elektrodynamische Wechselwirkung zwischen einem Magneten und einem Leiter. Das beobachtbare Phänomen hängt hier nur ab von der Relativbewegung von Leiter und Magnet, während nach der üblichen Auffassung die beiden Fälle, daß der eine oder der andere dieser Körper der bewegte sei, streng voneinander zu trennen sind. Bewegt sich nämlich der Magnet und ruht der Leiter, so entsteht in der Umgebung des Magneten ein elektrisches Feld von gewissem Energiewerte, welches an den Orten, wo sich Teile des Leiters befinden, einen Strom erzeugt. Ruht aber der Magnet und bewegt sich der Leiter, so entsteht in der Umgebung des Magneten kein elektrisches Feld, dagegen im Leiter eine elektromotorische Kraft, welcher an sich keine Energie entspricht, die aber — Gleichheit der Relativbewegung bei den beiden ins Auge gefaßten Fällen vorausgesetzt — zu elektrischen Strömen von derselben Größe und demselben Verlaufe Veranlassung gibt, wie im ersten Falle die elektrischen Kräfte.

Beispiele ähnlicher Art, sowie die mißlungenen Versuche, eine Bewegung der Erde relativ zum „Lichtmedium" zu konstatieren, führen zu der Vermutung, daß dem Begriffe der absoluten Ruhe nicht nur in der Mechanik, sondern auch in der Elektrodynamik keine Eigenschaften der Erscheinungen entsprechen, sondern daß vielmehr für alle Koordinatensysteme, für welche die mechanischen Gleichungen gelten, auch die gleichen elektrodynamischen und optischen Gesetze gelten, wie dies für die Größen erster Ordnung bereits erwiesen ist. Wir wollen diese Vermutung (deren Inhalt im folgenden „Prinzip der Relativität" genannt werden wird) zur Voraussetzung erheben und außerdem die mit ihm nur scheinbar unverträgliche

1. *Die Grundlage der allgemeinen Relativitätstheorie;*
von A. Einstein.

Die im nachfolgenden dargelegte Theorie bildet die denkbar weitgehendste Verallgemeinerung der heute allgemein als „Relativitätstheorie" bezeichneten Theorie; die letztere nenne ich im folgenden zur Unterscheidung von der ersteren „spezielle Relativitätstheorie" und setze sie als bekannt voraus. Die Verallgemeinerung der Relativitätstheorie wurde sehr erleichtert durch die Gestalt, welche der speziellen Relativitätstheorie durch Minkowski gegeben wurde, welcher Mathematiker zuerst die formale Gleichwertigkeit der räumlichen Koordinaten und der Zeitkoordinate klar erkannte und für den Aufbau der Theorie nutzbar machte. Die für die allgemeine Relativitätstheorie nötigen mathematischen Hilfsmittel lagen fertig bereit in dem „absoluten Differentialkalkül", welcher auf den Forschungen von Gauss, Riemann und Christoffel über nichteuklidische Mannigfaltigkeiten ruht und von Ricci und Levi-Civita in ein System gebracht und bereits auf Probleme der theoretischen Physik angewendet wurde. Ich habe im Abschnitt B der vorliegenden Abhandlung alle für uns nötigen, bei dem Physiker nicht als bekannt vorauszusetzenden mathematischen Hilfsmittel in möglichst einfacher und durchsichtiger Weise entwickelt, so daß ein Studium mathematischer Literatur für das Verständnis der vorliegenden Abhandlung nicht erforderlich ist. Endlich sei an dieser Stelle dankbar meines Freundes, des Mathematikers Grossmann, gedacht, der mir durch seine Hilfe nicht nur das Studium der einschlägigen mathematischen Literatur ersparte, sondern mich auch beim Suchen nach den Feldgleichungen der Gravitation unterstützte.

Over the period 1892–1905, Hendrik Lorentz (Dutch, 1853–1928, 1902 Nobel Prize in Physics—p. 891) developed mathematical formulas for apparent distortions of time and space for objects moving at nearly the speed of light. Those formulas for the distortions are now know as the Lorentz transformations, and they correctly describe special relativistic effects, as Einstein showed. Physicist Robert Weber described Lorentz's contributions to relativity [Weber 1988, pp. 12–13]:

> In 1892 Lorentz put forward the theory of electrons which profoundly influenced the development of theoretical physics. In 1895 he published his mathematical investigation of the effect on the shape of a body produced by its moving with speed v through the ether. [...] Ten years later this result was shown to follow from the theory of relativity.
>
> One deduction from Lorentz's electron theory of matter was that the mass of an electron increased with its velocity. Later experiments with beta rays from radioactive elements confirmed quantitatively his prediction, and once again Lorentz anticipated a finding of the theory of relativity. [...]
>
> In 1904 Lorentz made his greatest contribution to theoretical physics when he showed that James Clerk Maxwell's electromagnetic equations were not invariant with respect to velocity when transformed from one reference frame to another by the hitherto universally accepted Newtonian transformation formulae. These related the time and position coordinates of an event in one reference frame to those assigned to the same event viewed in another frame. Lorentz devised alternative transformation formulae which made Maxwell's equations invariant. Einstein, refusing to believe that there could be one set of such formulae (Newton's) for mechanical relationships and another (Lorentz's) for electrical, accepted Lorentz's transformation formulae as universally applicable. The special or restricted theory of relativity followed from that acceptance.

Actually, Woldemar Voigt (German, 1850–1919) correctly calculated the Lorentz transformations of space and time even earlier, in 1887, although he apparently did not fully consider their physical meaning or effects as in special relativity. Historians of science Christa Jungnickel and Russell McCormmach included a brief mention of Voigt's achievement in their history of early German physics [Jungnickel and McCormmach 1986, Vol. 2, p. 273]:

> In 1915, in honor of the tenth anniversary of the theory of relativity, the editors of the *Physikalische Zeitschrift* reprinted a paper of Voigt's from 1887 on the Doppler principle. This "very early precursor" of relativity theory contained what became known as the Lorentz transformations, which Voigt had derived from a study of the elastic light-ether. Physicists liked to recall this independent discovery, a curiosity that pointed up Voigt's remove from the developments that "modern" physics came to be identified with.
>
> Voigt had reservations about Einstein's relativity principle as a natural law[...]

Ernst Mach (Austrian, 1838–1916) intensively studied the physics of objects approaching or moving faster than the speed of sound waves. (Hence the Mach number of an object is the ratio of its speed to the speed of sound.) However, many of his results carry over to consideration of what would happen if objects approached or moved faster than the speed of light waves. Mach's philosophical approach to space and time also influenced Einstein's development of relativity, as described by historian Volker Berghahn [Berghahn 2005, p. 161]:

> Among the first to do so was Ernst Mach in Vienna who, in light of recent developments, proposed a total separation of metaphysics from the sciences. In his book *Die Mechanik in ihrer Entwicklung* (1883) he even went so far as to portray time and space as metaphysical concepts that should be thrown overboard. Nature, he wrote, did not know such confines. The body's temporal and spatial position was determined only in relation to other objects. Influenced by Mach, Einstein took the final step on this journey[...]

After Einstein worked out the physics and effects of special relativity, in 1907 Hermann Minkowski (German, 1864–1909) showed that those effects could be interpreted as the geometric behavior of four dimensions in which the three spatial dimensions are real numbers and the fourth or time dimension is an imaginary number (or equivalently, spatial dimensions are imaginary numbers and time is a real number). Physicist Abraham Pais summarized Minkowski's contributions [Pais 1982, pp. 151–152]:

> In 1902, Minkowski, at one time Einstein's teacher in Zürich, had moved to the University of Goettingen. There, on November 5, 1907, he gave a colloquium about relativity in which he identified Lorentz transformations with pseudorotations for which
>
> $$x_1^2 + x_2^2 + x_3^2 + x_4^2 \text{ is invariant,} \qquad x_4 = ict$$
>
> where x_1, x_2, x_3 denote the spatial variables. [...] Soon thereafter Minkowski published a detailed paper in which for the first time the Maxwell-Lorentz equations are presented in their modern tensor form, the equations of point mechanics are given a similar treatment, and the inadequacy of the Newtonian gravitation theory from the relativistic point of view is discussed. Terms such as *spacelike vector*, *timelike vector*, *light cone*, and *world line* stem from this paper.
>
> Thus began the enormous formal simplification of special relativity. Initially, Einstein was not impressed and regarded the transcriptions of his theory into tensor form as 'überflüssige Gelehrsamkeit,' (superfluous learnedness). However, in 1912 he adopted tensor methods and in 1916 acknowledged his indebtedness to Minkowski for having greatly facilitated the transition from special to general relativity.

Walter Kaufmann (German, 1871–1947) experimentally demonstrated that the mass of electrons increases with their velocity, as predicted by special relativity. He actually made his first measurements in 1901, before Einstein's first paper on relativity. Immediately after Einstein published his theory, Kaufmann made more accurate measurements of the electron mass increase in 1905. Alfred Bucherer (German, 1863–1927) made even more precise measurements in 1908, helping to distinguish between Einstein's version of special relativity and competing theories of electron mass increases.

To sum up the history of special relativity, Einstein justifiably earned the greatest credit for special relativity, through his discoveries about the physical origins and physical implications of space and time changing with velocity and his 1905 publications that elegantly tied all of that together. Yet if Einstein had never existed, these ideas were percolating within the German-speaking physics community, and it seems likely that Lorentz, Voigt, Minkowski, or others from that community would have arrived at the complete theory of special relativity within a few years after 1905.

5.3.2 General Relativity

General relativity covers the general case in which objects may be accelerating or decelerating. The forces inside an accelerating object are indistinguishable from the forces inside a gravitational field, so general relativity describes the weird things that happen when something gets close to very strong gravitational fields, such as time and space being warped (Fig. 5.32). Important effects that are correctly predicted by general relativity include the gravitational fields of stars, black holes, and wormholes; gravitational red-shifting of light; gravitational bending of light; precession of Mercury's perihelion as it orbits the sun; gravitational waves; and the overall structure and history of the universe.

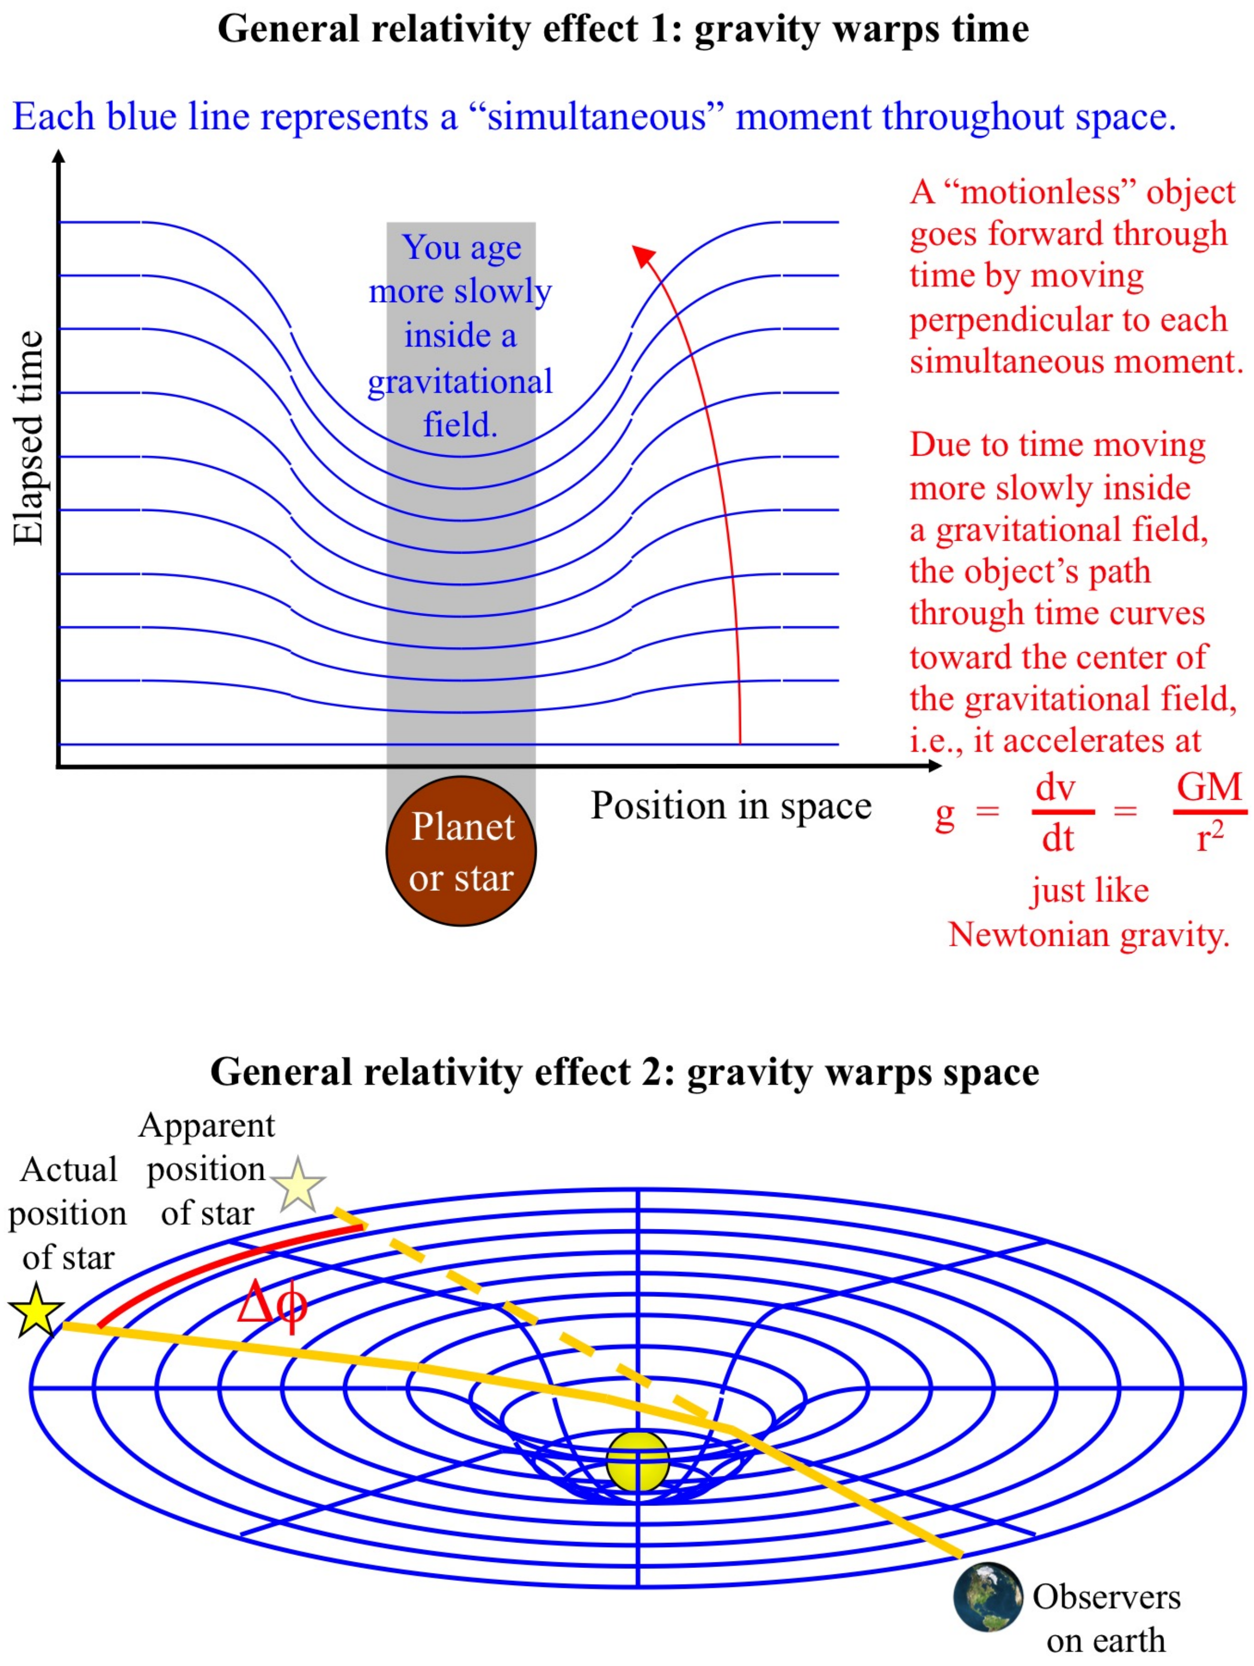
While Einstein was the dominant figure in special relativity, it is even more evident that he was the primary discoverer of general relativity. Kip Thorne, a Nobel-Prize-winning expert on general relativity, pointed out how extraordinarily farsighted and exceptional Einstein's work was [Thorne 1994, p. 119]:

> In fact, without Einstein the general relativistic laws of gravity might not have been discovered until several decades later.

While's Einstein's theory of relativity was never recognized by the Nobel Committee for Physics, the reaction from other scientists and from the public was overwhelming, as summarized by historians of science Jean Medawar and David Pyke [Medawar and Pyke 2000, p. 33]:

> Einstein was already famous, for his special theory of relativity produced in 1905 and his general theory published in 1917. However, they were still theories and not everyone was convinced. Then in 1919 an expedition, under the British physicist Sir Arthur Eddington, went to tropical Africa to photograph a total eclipse of the sun. This confirmed Einstein's prediction, made in 1917, by showing that light was bent by gravity. Almost universal acceptance followed and Einstein was hailed as a genius.
>
> In London, the discovery was announced by J. J. Thomson, President of the Royal Society, as 'one of the greatest achievements in the history of human thought'. Introducing the findings based on the expedition's photographs, Thomson continued: 'It is not the discovery of an outlying island but of a whole continent of new ideas. It is the greatest discovery in connection with gravity since Newton enunciated his principles.'
>
> Einstein became world-famous not only among scientists but also to the public. He was modest and of a tentative demeanour but that did not dampen the interest in everything he said and did. [...] He was honoured and fêted everywhere as the embodiment of science and the cleverest man in the world. No scientist had then, nor has since, been so admired or so famous.

Despite Einstein's critical role in the development of general relativity, a number of other German-speaking physicists and mathematicians also made important contributions to the theory, before, during, and after Einstein's work.



General relativity effect 1: gravity warps time
Each blue line represents a "simultaneous" moment throughout space.
Elapsed time
You age more slowly inside a gravitational field.
Planet or star
Position in space
A "motionless" object goes forward through time by moving perpendicular to each simultaneous moment.
Due to time moving more slowly inside a gravitational field, the object's path through time curves toward the center of the gravitational field, i.e., it accelerates at
$g = \frac{dv}{dt} = \frac{GM}{r^2}$
just like Newtonian gravity.
General relativity effect 2: gravity warps space
Actual position of star
Apparent position of star
$\Delta\phi$
Observers on earth

Figure 5.32: General relativity correctly predicts that gravitational fields warp both time and space, creating several measurable effects.

Just as Ernst Mach's ideas about space and time influenced Einstein's development of special relativity, Mach's ideas about inertia and acceleration also influenced Einstein's development of general relativity.

Likewise, Einstein incorporated Hermann Minkowski's ideas about the geometry of spatial and temporal dimensions, and his tensors for describing those mathematically, into the theory of general relativity.

Bernhard Riemann (German, 1826–1866) was the mathematician who originally developed most of the tensors and other mathematical methods of describing warped dimensions in general that Einstein later applied to describe warped space and time in particular.

Shortly after Riemann's death, Elwin Christoffel (German, 1829–1900) extended Riemann's work by adding some new tensors, now known as Christoffel symbols, to describe additional details of warped dimensions. Einstein ultimately incorporated the Christoffel symbols into general relativity, along with Riemann's tensors.

After Einstein's first papers on general relativity, the mathematician David Hilbert (German, 1862–1943) immersed himself in the new theory and independently published papers on the tensor mathematics of general relativity in parallel with Einstein's further papers on the topic. Gustav Herglotz (Austrian/German, 1881–1953) also published some independent and very early analyses of the tensor methods Einstein was using for general relativity.

As soon as Einstein's first equations for general relativity were available, Einstein, as well as Josef Lense (Austrian, 1890–1985) and Hans Thirring (Austrian, 1888–1976), found that in addition to the distortions of space and time caused by a massive object, if that object is rotating, it will also introduce "twisting" distortions into space and time. The twisting of space and time around massive rotating objects is called the Lense-Thirring effect or sometimes the Einstein-Lense-Thirring effect. Cornelius Lanczos (Hungarian, 1893–1974) and Willem Jacob van Stockum (Dutch, 1910–1944) later found that the spacetime twisting around massive rotating objects could be so extreme under certain circumstances that it might allow travel backward in time for someone circling in the right direction.

Loránd Eötvös (Austro-Hungarian, 1848–1919) conducted early experiments demonstrating the equivalence between gravity and acceleration, or the equivalence between gravitational mass and inertial mass. He also developed extremely sensitive methods of measuring gravitational gradients or variations along the earth's surface. The cgs unit for gravitational gradients is named in his honor, and Einstein cited Loránd Eötvös's experimental results when he published his theory of general relativity.

Immediately after Einstein published his first papers on general relativity in 1915, Karl Schwarzschild (German, 1873–1916) used those to solve the equations of general relativity for the gravitational field of a spherical, non-rotating mass. Einstein was impressed by his solution, and it is still widely used to describe the gravitational field of objects ranging from planets to black holes. The Schwarzschild radius, which appears in Schwarzschild's general mathematical solution, is the size to which a given mass must be compressed to form a black hole. Equivalently, the Schwarzschild radius is the distance from the center of the black hole to the point of no return (also called the event horizon) for objects near the black hole, where the gravitational field becomes so strong that not even light can escape from falling toward the center. If Schwarzschild had not died almost immediately after publishing his result, he might have gone on to make many more contributions to general relativity. Physicist Abraham Pais summarized Schwarzschild's contributions [Pais 1982, p. 255]:

> [O]n January 16, 1916, Einstein read a paper before the Prussian Academy on behalf of Karl Schwarzschild, who was in the German army at the Russian front at that time. The paper contained the exact solution of the static isotropic gravitational field of a mass point, the first instance of a rigorous solution of Einstein's full gravitational field equations. On February 24, 1916, Einstein read another paper by Schwarzschild, this one giving the solution for a mass point in the gravitational field of an incompressible fluid sphere. It is there that the Schwarzschild radius is introduced for the first time. On June 29, 1916, Einstein addressed the Prussian Academy to commemorate Schwarzschild, who had died on May 11 after a short illness contracted at the Russian front. He spoke of Schwarzschild's great talents and contributions both as an experimentalist and a theorist. He also spoke of Schwarzschild's achievements as director (since 1909) of the astrophysical observatory in Potsdam. He concluded by expressing his conviction that Schwarzschild's contributions would continue to play a stimulating role in science.

The same year (1916) that Schwarzschild published his solution for uncharged nonrotating black holes, Hans Reissner (German, 1874–1967) published the solution for charged nonrotating black holes. Gunnar Nordström (Finnish but very closely coupled to the German physics community, 1881–1923) and Hermann Weyl (German, 1885–1955) did further work on this solution.

Likewise, Ludwig Flamm (Austrian, 1885–1964) also responded to Einstein's first papers on general relativity by considering gravitational field solutions for specific cases in 1916. In particular, Flamm considered possible solutions for what would now be regarded as wormholes, or tunnels of warped space and time connecting two different parts of the universe. Hermann Weyl, Einstein, and Nathan Rosen (one of Einstein's close collaborators) later did further mathematical analysis of these wormhole solutions (which were ultimately dubbed Einstein-Rosen bridges).

The astronomer Erwin Finlay-Freundlich (German, 1885–1964) planned some of the first experimental tests of general relativity, including red-shifting of light from the sun and bending of starlight around the sun. Other scientists later carried out those tests and ultimately proved that general relativity was correct.

Gunnar Nordström, Theodor Kaluza (German, 1885–1954), and Oskar Klein (Swedish but very closely coupled to the German physics community, 1894–1977) considered how to extend Einstein's theory of general relativity to include extra dimensions and other forces such as electromagnetism.

Willem de Sitter (Dutch, 1872–1934) collaborated with Einstein to apply general relativity to describe various possible scenarios for the structure and history of the universe, and they both agreed that the equations of general relativity appeared to predict an expanding (or possibly contracting) universe. Historian Thomas Levenson wrote about the first interactions of de Sitter and Einstein regarding the theoretical discovery that the universe could be expanding [Levenson 2003, p. 135]:

> In February 1917 Willem De Sitter, professor of astronomy at the University of Leyden in the Netherlands, responded to Einstein's theory almost as soon as it appeared by

> proposing a model of an expanding universe. Einstein looked for some flaw in De Sitter's work that could rule out so unsettling a notion, but he soon gave up and admitted that there was nothing formally wrong with the idea.

In a series of 1918–1924 publications (Fig. 5.33), Carl Wilhelm Wirtz (German, 1876–1939) measured the distances and the red-shifting of light from other galaxies. The amount of red shift or Doppler shift indicated the galaxies' velocities relative to the Earth. With that data, he experimentally demonstrated that the universe was indeed expanding, and that more distant galaxies were moving away from us faster than galaxies closer to us, in agreement with de Sitter's and Einstein's predictions [Wirtz 1918, 1922a, 1922b, 1924, 1936]. Wirtz's first results in this area occurred more than a decade before Edwin Hubble's (American, 1889–1953) first 1929 paper that also showed evidence of the expanding universe. For example, in October 1921 Wirtz wrote [Wirtz 1922a]:

> Alle diese statistischen Erscheinungen lagern sich über den auffälligsten und Hauptvorgang, der sich als ein Auseinandertreiben des Systems den Spiralnebel relativ zu unserm Standpunkt beschreiben läßt. Dann bedeutet z.B. die Abhängigkeit von der galaktischen Breite, daß die Nebel bei den Polen sich rascher von uns entfernen als die Nebel der niedrigeren Breiten, und die Abhängigkeit von der Größenklasse zeigt an, daß die uns nächsten oder auch die massenstarken Spiralnebel eine geringere Auswärtsbewegung besitzen als die fernen oder etwa die massenschwachen Nebel. Daß der Zielpunkt aus den Radialbewegungen der Spiralnebel nichts zu tun hat mit dem Sonnenapex, ist bekannt.

> All of these statistical data result from the most remarkable and main process, which can be described as a driving apart of the system of the spiral galaxies relative to our point of view. Then for example the dependence on the galactic latitude means that the galaxies at the poles move away from us faster than the galaxies of the lower latitudes, and the dependence on the distance indicates that the spiral galaxies closest to us or perhaps the more massive galaxies have a smaller outward movement than the distant or the less massive galaxies. It is known that the target point from the radial movements of the spiral galaxies has nothing to do with the solar apex.

Several years after Wirtz's discovery and publications, Edwin Hubble aggressively promoted himself in public as the discoverer of the expanding universe, and Wirtz's accomplishments have unfortunately been nearly forgotten by history [Kragh and Smith 2003; Seitter and Duerbeck 1999; van den Bergh 2011]. Astronomer Sidney van den Bergh described the situation [van den Bergh 2011]:

> In his 1922 paper Wirtz concludes that either the nearest or the most massive galaxies have the lowest redshifts. From the more extensive observational material available in 1924 Wirtz found that the radial velocities of spiral nebulae grow quite significantly with increasing distance. He was aware of the fact that the General Theory of Relativity predicted that redshifts should increase with increasing distance. Wirtz published his results in the Astronomische Nachrichten, the leading German astronomy journal. (Hubble received an A in his high-school German course [...] and he also read German text books on corporate law [...] so he would have had no trouble reading Wirtz's papers.) [...]
>
> The myth that Hubble discovered the velocity-distance relation seems to have originated with Humason (1931) (who was at that time acting as Hubble's observing assistant).

Thus not only did Hubble's first papers on the expanding universe come more than a decade after Wirtz's first papers on that topic, but there are good reasons to believe that Hubble read the *Astronomische Nachrichten* journal containing Wirtz's papers, repeated Wirtz's astronomical observations, and tried to claim the discovery as his own while not mentioning Wirtz. If that is what happened, then Hubble was actually guilty of gross scientific misconduct. Books of scientific history should be rewritten to give proper credit to Wirtz, not Hubble.

George Gamow (Russian but educated and worked in Germany, lived 1904–1968) built on the earlier work of Einstein, de Sitter, Wirtz, and others regarding the history of the universe. Gamow considered the implications that the universe has been expanding outward ever since a "Big Bang" billions of years ago. Gamow made specific predictions about what evidence such a Big Bang would have produced (such as the production of certain amounts of nuclei and of electromagnetic "echoes" or background radiation) that were later discovered in experiments to be correct.

Following Einstein, de Sitter, and Wirtz, other theoretical physicists also took up the idea of an expanding universe: Alexander Friedman (Russian but published in German, 1888–1925) in 1924, Georges Lemaître (Belgian, 1894–1966) beginning in 1927, and Howard Robertson (American but trained in Germany, 1903–1961) and Arthur Walker (British, 1909–2001) in the 1930s.

In addition to his other predictions, in 1917 Einstein also predicted the properties and physical implications of what he called a "cosmological constant," but what is now called "dark energy," a diffuse field throughout the universe that acts to oppose the attraction of gravity [Pais 1982]. The first experimental evidence of dark energy was detected over 80 years later, in 1998, and much more evidence has been discovered since then (Fig. 4.61).

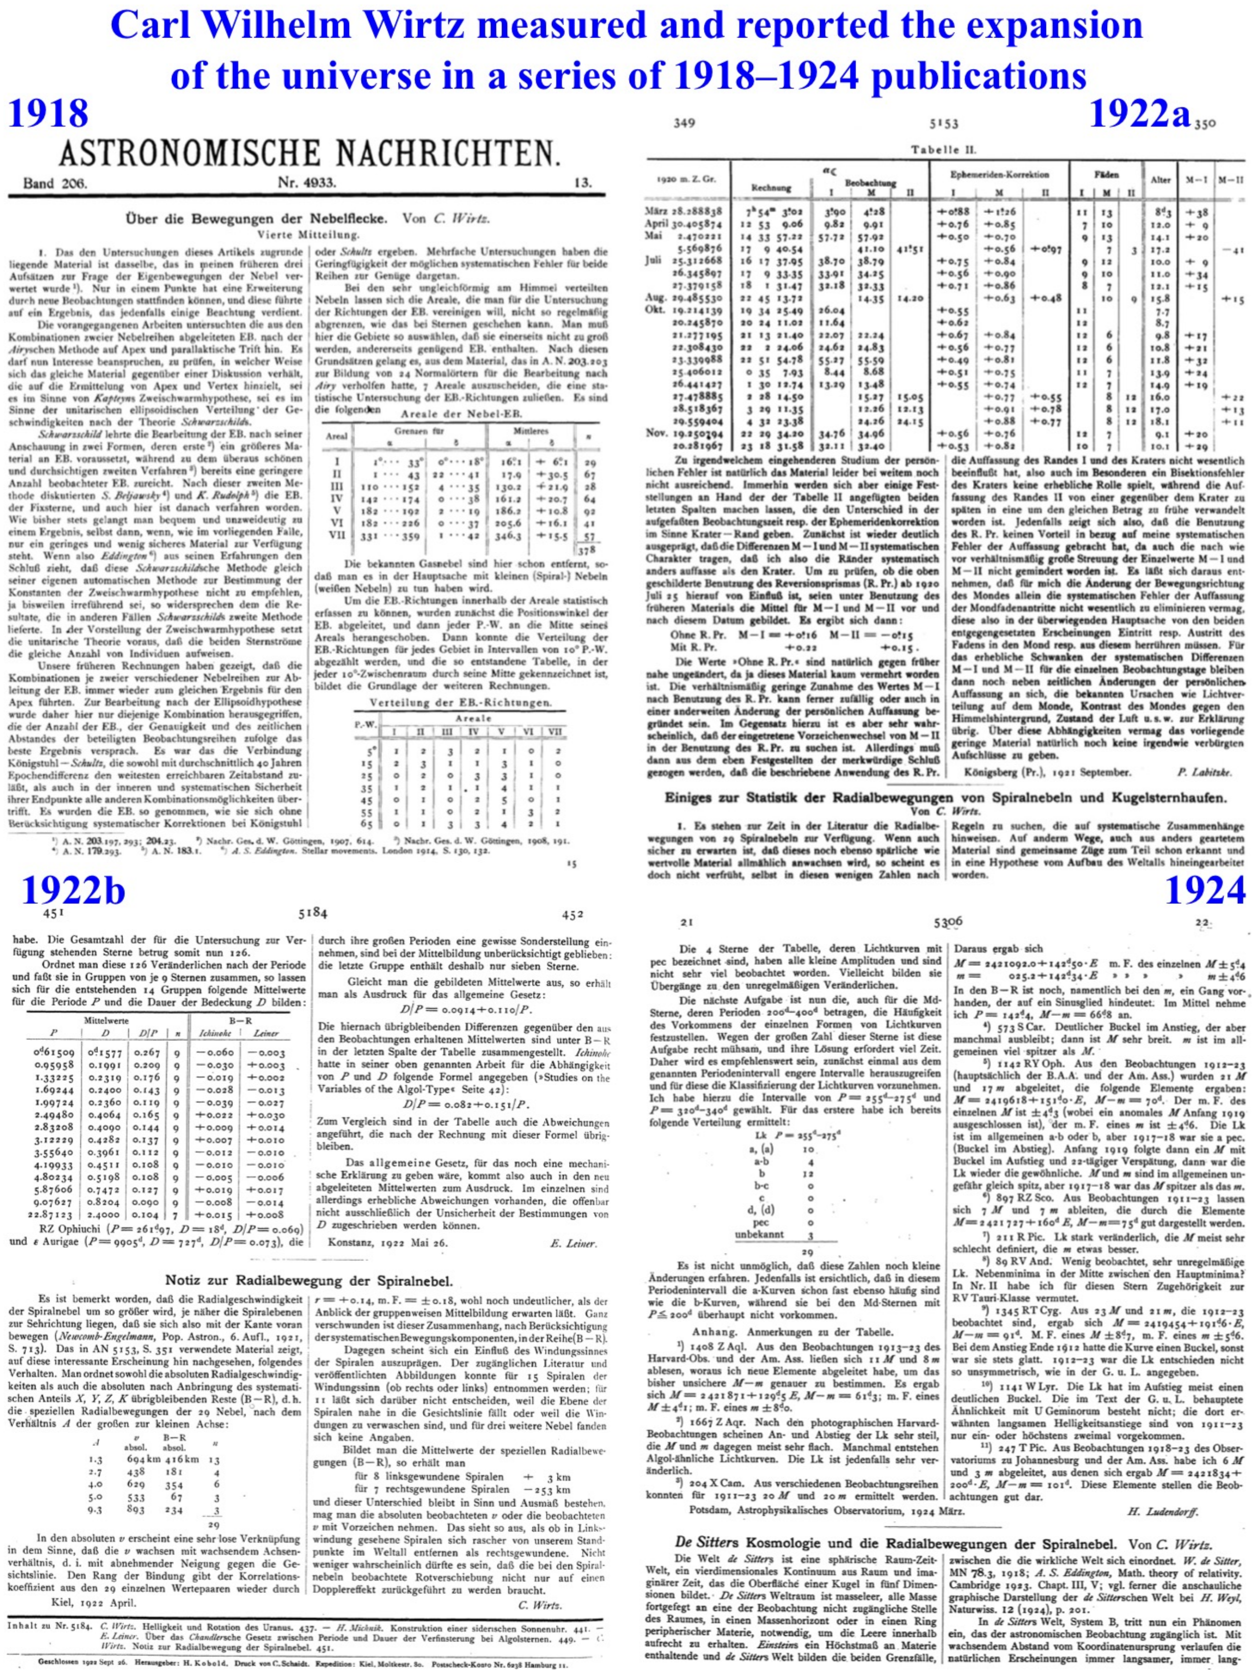
Jacobus Kapteyn (Dutch, 1851–1922), Fritz Zwicky (Swiss, 1898–1974), and Jan Oort (Dutch, 1900–1992) predicted dark matter, mysterious material that adds to the gravitational attraction of the universe but does not appear to be made out of known types of particles, decades before its existence was proven experimentally [John Johnson, Jr., 2019; Stöckli and Müller 2008]. Large amounts of evidence for the existence of dark matter were finally found in the 1970s and 1980s (Fig. 4.60).

Both dark energy and dark matter have had a decisive effect on the history and current state of our entire universe.

Hermann Bondi (Austrian, 1919–2005) and Thomas Gold (Austrian, 1920–2004) used general relativity to analyze a wide range of scenarios such as gravity waves, black holes, and the structure and history of the universe.

In the final decades of Einstein's life, Valentine Bargmann (German, 1908–1989) and Peter Bergmann (German, 1915–2002) collaborated with him on a number of possible extensions and applications of general relativity. Leopold Infeld (Austrian, 1898–1968) also collaborated with Einstein on how to calculate the motions of a large number of objects interacting with each other due to gravity.

For additional information on German-speaking contributions to astrophysics, see Section 4.6.



Carl Wilhelm Wirtz measured and reported the expansion of the universe in a series of 1918–1924 publications

1918

ASTRONOMISCHE NACHRICHTEN.

Band 206. Nr. 4933. 13.

Über die Bewegungen der Nebelflecke. Von *C. Wirtz.*

Vierte Mitteilung.

1. Das den Untersuchungen dieses Artikels zugrunde liegende Material ist dasselbe, das in meinen früheren drei Aufsätzen zur Frage der Eigenbewegungen der Nebel verwertet wurde[1]). Nur in einem Punkte hat eine Erweiterung durch neue Beobachtungen stattfinden können, und diese führte auf ein Ergebnis, das jedenfalls einige Beachtung verdient.

Die vorangegangenen Arbeiten untersuchten die aus den Kombinationen zweier Nebelreihen abgeleiteten EB. nach der *Airy*schen Methode auf Apex und parallaktische Trift hin. Es darf nun Interesse beanspruchen, zu prüfen, in welcher Weise sich das gleiche Material gegenüber einer Diskussion verhält, die auf die Ermittelung von Apex und Vertex hinzielt, sei es im Sinne von *Kapteyns* Zweischwarmhypothese, sei es im Sinne der unitarischen ellipsoidischen Verteilung der Geschwindigkeiten nach der Theorie *Schwarzschilds*.

Schwarzschild lehrte die Bearbeitung der EB. nach seiner Anschauung in zwei Formen, deren erste[2]) ein größeres Material an EB. voraussetzt, während zu dem überaus schönen und durchsichtigen zweiten Verfahren[3]) bereits eine geringere Anzahl beobachteter EB. zureicht. Nach dieser zweiten Methode diskutierten *S. Beljawsky*[4]) und *K. Rudolph*[5]) die EB. der Fixsterne, und auch hier ist danach verfahren worden. Wie bisher stets gelangt man bequem und unzweideutig zu einem Ergebnis, selbst dann, wenn, wie im vorliegenden Falle, nur ein geringes und wenig sicheres Material zur Verfügung steht. Wenn also *Eddington*[6]) aus seinen Erfahrungen den Schluß zieht, daß diese *Schwarzschild*sche Methode gleich seiner eigenen automatischen Methode zur Bestimmung der Konstanten der Zweischwarmhypothese nicht zu empfehlen, ja bisweilen irreführend sei, so widersprechen dem die Resultate, die in anderen Fällen *Schwarzschilds* zweite Methode lieferte. In der Vorstellung der Zweischwarmhypothese setzt die unitarische Theorie voraus, daß die beiden Sternströme die gleiche Anzahl von Individuen aufweisen.

Unsere früheren Rechnungen haben gezeigt, daß die Kombinationen je zweier verschiedener Nebelreihen zur Ableitung der EB. immer wieder zum gleichen Ergebnis für den Apex führten. Zur Bearbeitung nach der Ellipsoidhypothese wurde daher hier nur diejenige Kombination herausgegriffen, die der Anzahl der EB., der Genauigkeit und des zeitlichen Abstandes der beteiligten Beobachtungsreihen zufolge das beste Ergebnis versprach. Es war das die Verbindung Königstuhl—*Schultz*, die sowohl mit durchschnittlich 40 Jahren Epochendifferenz den weitesten erreichbaren Zeitabstand zuläßt, als auch in der inneren und systematischen Sicherheit ihrer Endpunkte alle anderen Kombinationsmöglichkeiten übertrifft. Es wurden die EB. so genommen, wie sie sich ohne Berücksichtigung systematischer Korrektionen bei Königstuhl oder *Schultz* ergeben. Mehrfache Untersuchungen haben die Geringfügigkeit der möglichen systematischen Fehler für beide Reihen zur Genüge dargetan.

Bei den sehr ungleichförmig am Himmel verteilten Nebeln lassen sich die Areale, die man für die Untersuchung der Richtungen der EB. vereinigen will, nicht so regelmäßig abgrenzen, wie das bei Sternen geschehen kann. Man muß hier die Gebiete so auswählen, daß sie einerseits nicht zu groß werden, andererseits genügend EB. enthalten. Nach diesen Grundsätzen gelang es, aus dem Material, das in A. N. **203**.203 zur Bildung von 24 Normalörtern für die Bearbeitung nach *Airy* verholfen hatte, 7 Areale auszuscheiden, die eine statistische Untersuchung der EB.-Richtungen zuließen. Es sind die folgenden

Areale der Nebel-EB.

Areal	Grenzen für α	Grenzen für δ	Mittleres α	Mittleres δ	n
I	1°···33°	0°···18°	16°.1	+6°.1	29
II	1···43	22···41	17.9	+30.5	67
III	110···152	4···35	130.2	+21.9	28
IV	142···174	0···38	161.2	+20.7	64
V	182···192	2···19	186.2	+10.8	92
VI	182···226	0···37	205.6	+16.1	41
VII	331···359	1···42	346.3	+15.5	57
					378

Die bekannten Gasnebel sind hier schon entfernt, sodaß man es in der Hauptsache mit kleinen (Spiral-) Nebeln (weißen Nebeln) zu tun haben wird.

Um die EB.-Richtungen innerhalb der Areale statistisch erfassen zu können, wurden zunächst die Positionswinkel der EB. abgeleitet, und dann jeder P.-W. an die Mitte seines Areals herangeschoben. Dann konnte die Verteilung der EB.-Richtungen für jedes Gebiet in Intervallen von 10° P.-W. abgezählt werden, und die so entstandene Tabelle, in der jeder 10°-Zwischenraum durch seine Mitte gekennzeichnet ist, bildet die Grundlage der weiteren Rechnungen.

Verteilung der EB.-Richtungen.

P.-W.	Areale I	II	III	IV	V	VI	VII
5°	1	2	3	2	1	0	2
15	2	3	1	1	3	1	0
25	0	2	0	3	3	1	0
35	1	2	1	1	4	1	1
45	0	1	0	2	5	0	1
55	1	1	0	2	1	3	2
65	0	1	3	3	4	2	1

Zu irgendwelchem eingehenderen Studium der persönlichen Fehler ist natürlich das Material leider bei weitem noch nicht ausreichend. Immerhin werden sich aber einige Feststellungen an Hand der der Tabelle II angefügten beiden letzten Spalten machen lassen, die den Unterschied in der aufgefaßten Beobachtungszeit resp. der Ephemeridenkorrektion im Sinne Krater—Rand geben. Zunächst ist wieder deutlich ausgeprägt, daß die Differenzen M—I und M—II systematischen Charakter tragen, daß ich also die Ränder systematisch anders auffasse als den Krater. Um zu prüfen, ob die oben geschilderte Benutzung des Reversionsprismas (R. Pr.) ab 1920 Juli 25 hierauf von Einfluß ist, seien unter Benutzung des früheren Materials die Mittel für M—I und M—II vor und nach diesem Datum gebildet. Es ergibt sich dann:

Ohne R. Pr. M—I = $+0^s16$ M—II = -0^s15
Mit R. Pr. +0.22 +0.15.

Die Werte »Ohne R. Pr.« sind natürlich gegen früher nahe ungeändert, da ja dieses Material kaum vermehrt worden ist. Die verhältnismäßig geringe Zunahme des Wertes M—I nach Benutzung des R. Pr. kann ferner zufällig oder auch in einer anderweiten Änderung der persönlichen Auffassung begründet sein. Im Gegensatz hierzu ist es aber sehr wahrscheinlich, daß der eingetretene Vorzeichenwechsel von M—II in der Benutzung des R. Pr. zu suchen ist. Allerdings muß dann aus dem eben Festgestellten der merkwürdige Schluß gezogen werden, daß die beschriebene Anwendung des R. Pr. die Auffassung des Randes I und des Kraters nicht wesentlich beeinflußt hat, also auch im Besonderen ein Bisektionsfehler des Kraters keine erhebliche Rolle spielt, während die Auffassung des Randes II von einer gegenüber dem Krater zu späten in eine um den gleichen Betrag zu frühe verwandelt worden ist. Jedenfalls zeigt sich also, daß die Benutzung des R. Pr. keinen Vorteil in bezug auf meine systematischen Fehler der Auffassung gebracht hat, da auch die nach wie vor verhältnismäßig große Streuung der Einzelwerte M—I und M—II nicht gemindert worden ist. Es läßt sich daraus entnehmen, daß für mich die Änderung der Bewegungsrichtung des Mondes allein die systematischen Fehler der Auffassung der Mondfadenantritte nicht wesentlich zu eliminieren vermag, diese also in der überwiegenden Hauptsache von den beiden entgegengesetzten Erscheinungen Eintritt resp. Austritt des Fadens in den Mond resp. aus diesem herrühren müssen. Für das erhebliche Schwanken der systematischen Differenzen M—I und M—II für die einzelnen Beobachtungstage bleiben dann noch neben zeitlichen Änderungen der persönlichen Auffassung an sich, die bekannten Ursachen wie Lichtverteilung auf dem Monde, Kontrast des Mondes gegen den Himmelshintergrund, Zustand der Luft u. s. w. zur Erklärung übrig. Über diese Abhängigkeiten vermag das vorliegende geringe Material natürlich noch keine irgendwie verbürgten Aufschlüsse zu geben.

Königsberg (Pr.), 1921 September. *P. Labitzke.*

Einiges zur Statistik der Radialbewegungen von Spiralnebeln und Kugelsternhaufen.

Von *C. Wirtz.*

1. Es stehen zur Zeit in der Literatur die Radialbewegungen von 29 Spiralnebeln zur Verfügung. Wenn auch sicher zu erwarten ist, daß dieses noch ebenso spärliche wie wertvolle Material allmählich anwachsen wird, so scheint es doch nicht verfrüht, selbst in diesen wenigen Zahlen nach Regeln zu suchen, die auf systematische Zusammenhänge hinweisen. Auf anderm Wege, auch aus anders geartetem Material sind gemeinsame Züge zum Teil schon erkannt und in eine Hypothese vom Aufbau des Weltalls hineingearbeitet worden.

1922b

451 5184 452

habe. Die Gesamtzahl der für die Untersuchung zur Verfügung stehenden Sterne betrug somit nun 126.

Ordnet man diese 126 Veränderlichen nach der Periode und faßt sie in Gruppen von je 9 Sternen zusammen, so lassen sich für die entstehenden 14 Gruppen folgende Mittelwerte für die Periode *P* und die Dauer der Bedeckung *D* bilden:

Mittelwerte *P*	*D*	*D/P*	*n*	B−R *Ichinohe*	B−R *Leiner*
0^d61509	0^d1577	0.267	9	−0.060	−0.003
0.95958	0.1991	0.209	9	−0.030	+0.003
1.33225	0.2319	0.176	9	−0.019	+0.002
1.69244	0.2400	0.143	9	−0.028	−0.013
1.99724	0.2360	0.119	9	−0.039	−0.027
2.49480	0.4064	0.165	9	+0.022	+0.030
2.83208	0.4090	0.144	9	+0.009	+0.014
3.12229	0.4282	0.137	9	+0.007	+0.010
3.55640	0.3961	0.112	9	−0.012	−0.010
4.19933	0.4511	0.108	9	−0.010	−0.010
4.80234	0.5198	0.108	9	−0.005	−0.006
5.87606	0.7472	0.127	9	+0.019	+0.017
9.07627	0.8204	0.090	9	−0.008	−0.014
22.87123	2.4000	0.104	7	+0.015	+0.008

RZ Ophiuchi ($P = 261^d97$, $D = 18^d$, $D/P = 0.069$) und ε Aurigae ($P = 9905^d$, $D = 727^d$, $D/P = 0.073$), die durch ihre großen Perioden eine gewisse Sonderstellung einnehmen, sind bei der Mittelbildung unberücksichtigt geblieben: die letzte Gruppe enthält deshalb nur sieben Sterne.

Gleicht man die gebildeten Mittelwerte aus, so erhält man als Ausdruck für das allgemeine Gesetz:

$$D/P = 0.0914 + 0.110/P.$$

Die hiernach übrigbleibenden Differenzen gegenüber den aus den Beobachtungen erhaltenen Mittelwerten sind unter B—R in der letzten Spalte der Tabelle zusammengestellt. *Ichinohe* hatte in seiner oben genannten Arbeit für die Abhängigkeit von *P* und *D* folgende Formel angegeben (»Studies on the Variables of the Algol-Type« Seite 42):

$$D/P = 0.082 + 0.151/P.$$

Zum Vergleich sind in der Tabelle auch die Abweichungen angeführt, die nach der Rechnung mit dieser Formel übrigbleiben.

Das allgemeine Gesetz, für das noch eine mechanische Erklärung zu geben wäre, kommt also auch in den neu abgeleiteten Mittelwerten zum Ausdruck. Im einzelnen sind allerdings erhebliche Abweichungen vorhanden, die offenbar nicht ausschließlich der Unsicherheit der Bestimmungen von *D* zugeschrieben werden können.

Konstanz, 1922 Mai 26. *E. Leiner.*

Notiz zur Radialbewegung der Spiralnebel.

Es ist bemerkt worden, daß die Radialgeschwindigkeit der Spiralnebel um so größer wird, je näher die Spiralebenen zur Sehrichtung liegen, daß sie sich also mit der Kante voran bewegen (*Newcomb-Engelmann*, Pop. Astron., 6. Aufl., 1921, S. 713). Das in AN 5153, S. 351 verwendete Material zeigt, auf diese interessante Erscheinung hin nachgesehen, folgendes Verhalten. Man ordnet sowohl die absoluten Radialgeschwindigkeiten als auch die absoluten nach Anbringung des systematischen Anteils *X*, *Y*, *Z*, *K* übrigbleibenden Reste (B—R), d. h. die speziellen Radialbewegungen der 29 Nebel, nach dem Verhältnis *A* der großen zur kleinen Achse:

A	*v* absol.	B−R absol.	*n*
1.3	694 km	416 km	13
2.7	438	181	4
4.0	629	354	6
5.0	533	67	3
9.3	893	234	3
			29

In den absoluten *v* erscheint eine sehr lose Verknüpfung in dem Sinne, daß die *v* wachsen mit wachsendem Achsenverhältnis, d. i. mit abnehmender Neigung gegen die Gesichtslinie. Den Rang der Bindung gibt der Korrelationskoeffizient aus den 29 einzelnen Wertepaaren wieder durch $r = +0.14$, m. F. $= \pm 0.18$, wohl noch undeutlicher, als der Anblick der gruppenweisen Mittelbildung erwarten läßt. Ganz verschwunden ist dieser Zusammenhang, nach Berücksichtigung der systematischen Bewegungskomponenten, in der Reihe (B—R).

Dagegen scheint sich ein Einfluß des Windungssinnes der Spiralen auszuprägen. Der zugänglichen Literatur und veröffentlichten Abbildungen konnte für 15 Spiralen der Windungssinn (ob rechts oder links) entnommen werden; für 11 läßt sich darüber nicht entscheiden, weil die Ebene der Spiralen nahe in die Gesichtslinie fällt oder weil die Windungen zu verwaschen sind, und für drei weitere Nebel fanden sich keine Angaben.

Bildet man die Mittelwerte der speziellen Radialbewegungen (B—R), so erhält man

für 8 linksgewundene Spiralen + 3 km
für 7 rechtsgewundene Spiralen −253 km

und dieser Unterschied bleibt in Sinn und Ausmaß bestehen, mag man die absoluten beobachteten *v* oder die beobachteten *v* mit Vorzeichen nehmen. Das sieht so aus, als ob in Linkswindung gesehene Spiralen sich rascher von unserem Standpunkte im Weltall entfernen als rechtsgewundene. Nicht weniger wahrscheinlich dürfte es sein, daß die bei den Spiralnebeln beobachtete Rotverschiebung nicht nur auf einen Dopplereffekt zurückgeführt zu werden braucht.

1924

21 5306 22

Die 4 Sterne der Tabelle, deren Lichtkurven mit pec bezeichnet sind, haben alle kleine Amplituden und sind nicht sehr viel beobachtet worden. Vielleicht bilden sie Übergänge zu den unregelmäßigen Veränderlichen.

Die nächste Aufgabe ist nun die, auch für die Md-Sterne, deren Perioden 200^d–400^d betragen, die Häufigkeit des Vorkommens der einzelnen Formen von Lichtkurven festzustellen. Wegen der großen Zahl dieser Sterne ist diese Aufgabe recht mühsam, und ihre Lösung erfordert viel Zeit. Daher wird es empfehlenswert sein, zunächst einmal aus dem genannten Periodenintervall engere Intervalle herauszugreifen und für diese die Klassifizierung der Lichtkurven vorzunehmen. Ich habe hierzu die Intervalle von $P = 255^d$–275^d und $P = 320^d$–340^d gewählt. Für das erstere habe ich bereits folgende Verteilung ermittelt:

Lk	$P = 255^d$–275^d
a, (a)	10
a-b	4
b	12
b-c	0
c	0
d, (d)	0
pec	0
unbekannt	3
	29

Es ist nicht unmöglich, daß diese Zahlen noch kleine Änderungen erfahren. Jedenfalls ist ersichtlich, daß in diesem Periodenintervall die a-Kurven schon fast ebenso häufig sind wie die b-Kurven, während sie bei den Md-Sternen mit $P \leq 200^d$ überhaupt nicht vorkommen.

Anhang. Anmerkungen zu der Tabelle.

[1]) 1408 Z Aql. Aus den Beobachtungen 1913–23 des Harvard-Obs. und der Am. Ass. ließen sich 11 *M* und 8 *m* ablesen, woraus ich neue Elemente abgeleitet habe, um das bisher unsichere *M*—*m* genauer zu bestimmen. Es ergab sich $M = 2421871 + 129^d5\,E$, $M - m = 61^d3$; m. F. eines $M \pm 4^d1$; m. F. eines $m \pm 8^d0$.

[2]) 1667 Z Aqr. Nach den photographischen Harvard-Beobachtungen scheinen An- und Abstieg der Lk sehr steil, die *M* und *m* dagegen meist sehr flach. Manchmal entstehen Algol-ähnliche Lichtkurven. Die Lk ist jedenfalls sehr veränderlich.

[3]) 204 X Cam. Aus verschiedenen Beobachtungsreihen konnten für 1911–23 20 *M* und 20 *m* ermittelt werden. Daraus ergab sich

$M = 2421092.0 + 142^d50 \cdot E$ m. F. des einzelnen $M \pm 5^d4$
$m = 025.2 + 142^d34 \cdot E$ » » » » $m \pm 4^d6$

In den B—R ist noch, namentlich bei den *m*, ein Gang vorhanden, der auf ein Sinusglied hindeutet. Im Mittel nehme ich $P = 142^d4$, $M - m = 66^d8$ an.

[4]) 573 S Car. Deutlicher Buckel im Anstieg, der aber manchmal ausbleibt; dann ist *M* sehr breit. *m* ist im allgemeinen viel spitzer als *M*.

[5]) 1142 RY Oph. Aus den Beobachtungen 1912–23 (hauptsächlich der B.A.A. und der Am. Ass.) wurden 21 *M* und 17 *m* abgeleitet, die folgende Elemente ergaben: $M = 2419618 + 151^d0 \cdot E$, $M - m = 70^d$. Der m. F. des einzelnen *M* ist $\pm 4^d3$ (wobei ein anomales *M* Anfang 1919 ausgeschlossen ist), der m. F. eines *m* ist $\pm 4^d6$. Die Lk ist im allgemeinen a-b oder b, aber 1917–18 war sie a pec. (Buckel im Abstieg). Anfang 1919 folgte dann ein *M* mit Buckel im Aufstieg und 22-tägiger Verspätung, dann war die Lk wieder die gewöhnliche. *M* und *m* sind im allgemeinen ungefähr gleich spitz, aber 1917–18 war das *M* spitzer als das *m*.

[6]) 897 RZ Sco. Aus Beobachtungen 1911–23 lassen sich 7 *M* und 7 *m* ableiten, die durch die Elemente $M = 2421727 + 160^d\,E$, $M - m = 75^d$ gut dargestellt werden.

[7]) 211 R Pic. Lk stark veränderlich, die *M* meist sehr schlecht definiert, die *m* etwas besser.

[8]) 89 RV And. Wenig beobachtet, sehr unregelmäßige Lk. Nebenminima in der Mitte zwischen den Hauptminima? In Nr. II habe ich für diesen Stern Zugehörigkeit zur RV Tauri-Klasse vermutet.

[9]) 1345 RT Cyg. Aus 23 *M* und 21 *m*, die 1912–23 beobachtet sind, ergab sich $M = 2419454 + 191^d6 \cdot E$, $M - m = 91^d$. M. F. eines $M \pm 8^d7$, m. F. eines $m \pm 5^d6$. Bei dem Anstieg Ende 1912 hatte die Kurve einen Buckel, sonst war sie stets glatt. 1912–23 war die Lk entschieden nicht so unsymmetrisch, wie in der G. u. L. angegeben.

[10]) 1141 W Lyr. Die Lk hat im Aufstieg meist einen deutlichen Buckel. Die im Text der G. u. L. behauptete Ähnlichkeit mit U Geminorum besteht nicht; die dort erwähnten langsamen Helligkeitsanstiege sind von 1911–23 nur ein- oder höchstens zweimal vorgekommen.

[11]) 247 T Pic. Aus Beobachtungen 1918–23 des Observatoriums zu Johannesburg und der Am. Ass. habe ich 6 *M* und 3 *m* abgeleitet, aus denen sich ergab $M = 2421834 + 200^d \cdot E$, $M - m = 101^d$. Diese Elemente stellen die Beobachtungen gut dar.

Potsdam, Astrophysikalisches Observatorium, 1924 März. *H. Ludendorff.*

De Sitters Kosmologie und die Radialbewegungen der Spiralnebel. Von *C. Wirtz.*

Die Welt *de Sitters* ist eine sphärische Raum-Zeit-Welt, ein vierdimensionales Kontinuum aus Raum und imaginärer Zeit, das die Oberfläche einer Kugel in fünf Dimensionen bildet. *De Sitters* Weltraum ist masseleer, alle Masse fortgefegt an eine der Beobachtung nicht zugängliche Stelle des Raumes, in einen Massenhorizont oder in einen Ring peripherischer Materie, notwendig, um die Leere innerhalb aufrecht zu erhalten. *Einsteins* ein Höchstmaß an Materie enthaltende und *de Sitters* Welt bilden die beiden Grenzfälle, zwischen die die wirkliche Welt sich einordnet. *W. de Sitter*, MN **78**.3, 1918; *A. S. Eddington*, Math. theory of relativity. Cambridge 1923. Chapt. III, V; vgl. ferner die anschauliche graphische Darstellung der *de Sitter*schen Welt bei *H. Weyl*, Naturwiss. 12 (1924), p. 201.

In *de Sitters* Welt, System B, tritt nun ein Phänomen ein, das der astronomischen Beobachtung zugänglich ist. Mit wachsendem Abstand vom Koordinatenursprung verlaufen die natürlichen Erscheinungen immer langsamer, immer lang-

Figure 5.33: Carl Wilhelm Wirtz measured and reported the expansion of the universe in a series of 1918–1924 publications [Wirtz 1918, 1922a, 1922b, 1924].

5.4 Non-Relativistic Quantum Physics

Like an Impressionist painting, matter looks clearly delineated and well behaved when seen macroscopically from a distance, but blurry and confusing when viewed microscopically at the level of individual atoms. (Non-relativistic) quantum physics describes the strange behavior of very small things. (Section 5.6 discusses relativistic quantum physics, the even stranger behavior when relativity and quantum physics are combined.)

As shown in Fig. 5.34, there are two fundamental ideas in quantum physics:

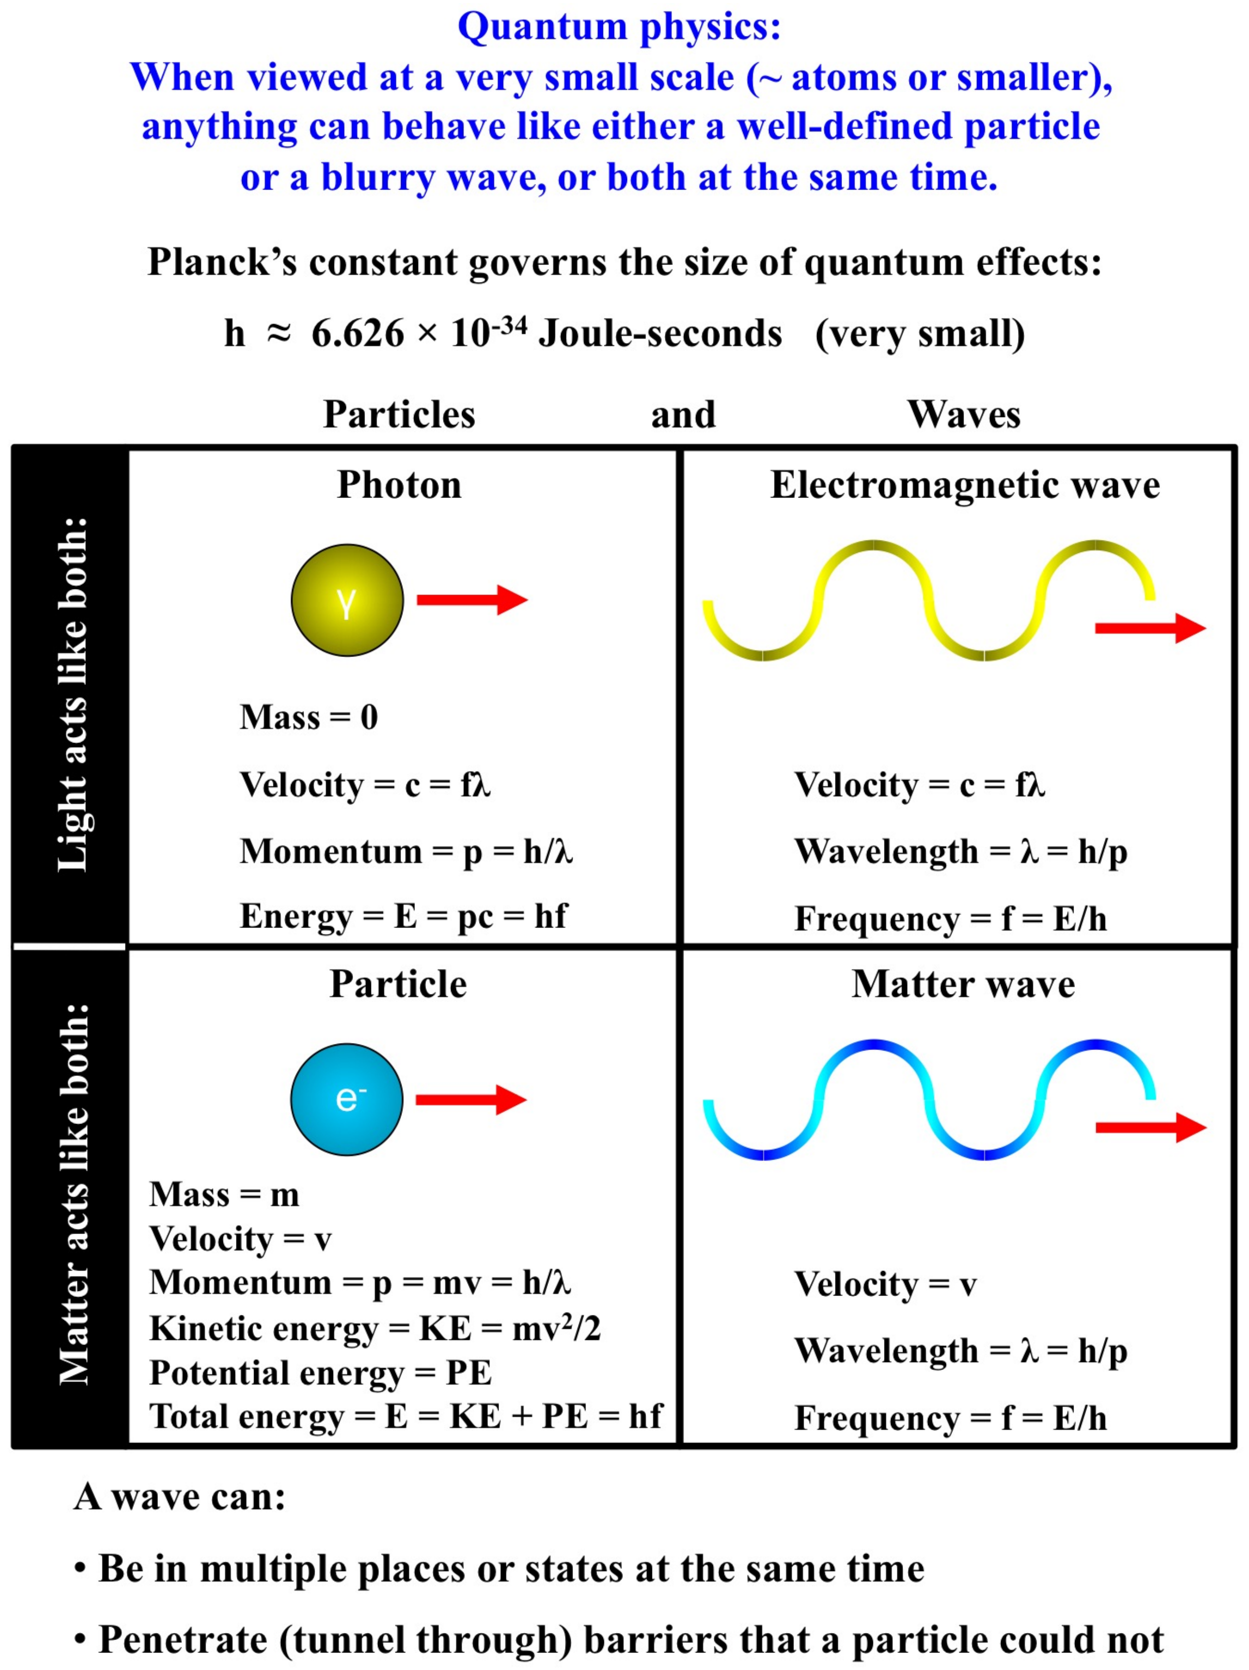
- What we normally think of as waves can act like particles; for example, electromagnetic waves can act like discrete particles called photons.
- Conversely, at the microscopic scale, particles of matter can act like blurry waves instead of discrete chunks of solid stuff.

Weird quantum effects of particles acting like waves (and vice versa) generally only happen with things the size of atoms or smaller, because the interrelationship between wave and particle behavior involves a very small physical constant (Planck's constant $h \approx 6.626 \times 10^{-34}$ Joule-seconds). Nevertheless, those quantum phenomena can have profound effects on the behavior of subatomic particles, atoms, and molecules, and therefore on any reactions (chemical or nuclear) in which they are involved, or devices (transistors, lasers, etc.) of which they are a part.

Like relativity, quantum physics was almost entirely a product of the German-speaking world (Figs. 5.35–5.39).[5] Perhaps the most significant contributions to quantum physics from outside the German-speaking world were those of the French physicist Louis de Broglie (1892–1987), who proposed the mathematical relationship between particle momentum and quantum wavelength, and the Danish physicist Niels Bohr (1885–1962), who proposed a simple quantum model of the atom and was closely connected with the German-speaking scientific world throughout his career. In fact, historians are generally in such agreement that quantum physics was primarily a product of the German-speaking world that they have spent decades debating what factors may have promoted that development [Carson et al. 2011].

---

[5] For good overviews of this area, see especially: Laurie Brown et al. 1995; Gamow 1966; Jones 2008; Jungnickel and McCormmach 1986, 2017; Kragh 2002; L'Annunziata 2016; von Meÿenn 1997; Weber 1988.



Quantum physics:
When viewed at a very small scale (~ atoms or smaller), anything can behave like either a well-defined particle or a blurry wave, or both at the same time.

Planck's constant governs the size of quantum effects:

h ≈ 6.626×10^{-34} Joule-seconds (very small)

Particles and Waves

	Particles	Waves
Light acts like both:	**Photon** Mass = 0 Velocity = c = fλ Momentum = p = h/λ Energy = E = pc = hf	**Electromagnetic wave** Velocity = c = fλ Wavelength = λ = h/p Frequency = f = E/h
Matter acts like both:	**Particle** Mass = m Velocity = v Momentum = p = mv = h/λ Kinetic energy = KE = $mv^2/2$ Potential energy = PE Total energy = E = KE + PE = hf	**Matter wave** Velocity = v Wavelength = λ = h/p Frequency = f = E/h

A wave can:

- **Be in multiple places or states at the same time**
- **Penetrate (tunnel through) barriers that a particle could not**

Figure 5.34: The central concept of quantum physics is that when the world is viewed at a very small scale (typically at the size of atoms or smaller), anything can behave like either a well-defined particle or a blurry wave, or both at the same time.

5.4.1 Early Steps Toward Quantum Theory

Arguably the first significant work on quantum theory was by Johann Balmer (Swiss, 1825–1898). In 1885, he developed a mathematical formula that correctly described the spacing between different wavelengths of light that could be emitted or absorbed by hydrogen atoms. Many years later, other scientists would show that the spacings Balmer described occurred because quantum physics only allowed certain electron orbits and energy levels in atoms, and therefore certain energies or wavelengths of light that could be emitted or absorbed by electrons transitioning between those atomic energy levels. In 1908, Friedrich Paschen (German, 1865–1947) also demonstrated that the spectral lines continue beyond visible wavelengths well into the infrared spectrum [Jungnickel and McCormmach 1986].

In 1900, Max Planck (German, 1858–1947) made a seminal discovery in quantum physics [Brandon Brown 2015; Planck 1950]. He showed that the spectrum of light and other electromagnetic radiation emitted by a hot object (a "black body" that glows because of its heat) could be explained if the electromagnetic radiation was acting not just as waves, but also as particles (later dubbed "photons"). Planck found that the energy E of the particles was proportional to the frequency f of the waves, where the two quantities were related by a new constant $h \approx 6.626 \times 10^{-34}$ Joule-seconds that came to be known as Planck's constant ($E = hf$). Later scientists would realize that Planck's constant governed a wide variety of quantum effects. Planck won the Nobel Prize in Physics in 1918 for his pioneering work. Dr. Å. G. Ekstrand, President of the Royal Swedish Academy of Sciences, announced the award [https://www.nobelprize.org/prizes/physics/1918/ceremony-speech/]:

> Professor Planck. The Swedish Academy of Sciences has awarded you the Nobel Prize for 1918 in recognition of your epoch-making investigations into the quantum theory. This theory, which was originally connected with black-body radiation, has now demonstrated its validity for other fields and relationships of Nature, and the constant number, named after you, is a proportionality factor which describes a common, but until now unknown, property of matter.

Albert Einstein (German, 1879–1955) expanded on Planck's work regarding how light behaves like quantum particles, or photons [Isaacson 2007; Pais 1982]. Specifically, Einstein showed that the particle nature of light could explain the photoelectric effect, in which there is a clear difference between particles of light that do or do not have enough energy to knock electrons loose in a substance. For helping to further establish and expand the growing field of quantum physics (but not for his contributions to statistical physics or his development of special and general relativity!), Einstein received the Nobel Prize in Physics in 1921. Professor S. Arrhenius, Chairman of the Nobel Committee for Physics, explained [https://www.nobelprize.org/prizes/physics/1921/ceremony-speech/]:

> There is probably no physicist living today whose name has become so widely known as that of Albert Einstein. Most discussion centres on his theory of relativity. This pertains essentially to epistemology and has therefore been the subject of lively debate in philosophical circles. It will be no secret that the famous philosopher Bergson in Paris has challenged this theory, while other philosophers have acclaimed it wholeheartedly. The theory in question also has astrophysical implications which are being rigorously examined at the present time.
>
> Throughout the first decade of this century the so-called Brownian movement stimulated the keenest interest. In 1905 Einstein founded a kinetic theory to account for this

> movement by means of which he derived the chief properties of suspensions, i.e. liquids with solid particles suspended in them. This theory, based on classical mechanics, helps to explain the behaviour of what are known as colloidal solutions, a behaviour which has been studied by Svedberg, Perrin, Zsigmondy and countless other scientists within the context of what has grown into a large branch of science, colloid chemistry.
>
> A third group of studies, for which in particular Einstein has received the Nobel Prize, falls within the domain of the quantum theory founded by Planck in 1900. This theory asserts that radiant energy consists of individual particles, termed "quanta", approximately in the same way as matter is made up of particles, i.e. atoms. This remarkable theory, for which Planck received the Nobel Prize for Physics in 1918, suffered from a variety of drawbacks and about the middle of the first decade of this century it reached a kind of impasse. Then Einstein came forward with his work on specific heat and the photoelectric effect. This latter had been discovered by the famous physicist Hertz in 1887. He found that an electrical spark passing between two spheres does so more readily if its path is illuminated with the light from another electrical discharge. A more exhaustive study of this interesting phenomenon was carried out by Hallwachs who showed that under certain conditions a negatively charged body, e.g. a metal plate, illuminated with light of a particular colour—ultraviolet has the strongest effect—loses its negative charge and ultimately assumes a positive charge. In 1899 Lenard demonstrated the cause to be the emission of electrons at a certain velocity from the negatively charged body. The most extraordinary aspect of this effect was that the electron emission velocity is independent of the intensity of the illuminating light, which is proportional only to the number of electrons, whereas the velocity increases with the frequency of the light. Lenard stressed that this phenomenon was not in good agreement with the then prevailing concepts. [...]
>
> Einstein's law of the photo-electrical effect has been extremely rigorously tested by the American Millikan and his pupils and passed the test brilliantly. Owing to these studies by Einstein the quantum theory has been perfected to a high degree and an extensive literature grew up in this field whereby the extraordinary value of this theory was proved. Einstein's law has become the basis of quantitative photo-chemistry in the same way as Faraday's law is the basis of electro-chemistry.

While some physicists were exploring various aspects of the wave/particle duality of light, other physicists were investigating aspects of what ultimately proved to be the wave/particle duality of electrons, as revealed by how the electrons orbiting in atoms emitted and absorbed light. Building on the earlier work by Johann Balmer about the behavior of normal atoms, they studied how atoms responded to strong magnetic or electric fields.

Pieter Zeeman (Dutch, 1865–1943) demonstrated and Hendrik Lorentz (Dutch, 1853–1928) explained how applied magnetic fields shift the energy levels of electrons orbiting in atoms, and therefore the wavelengths of light that they absorb and emit [Jungnickel and McCormmach 1986]. For this work, they both won the Nobel Prize in Physics in 1902. Professor Hj. Théel, President of the Royal Swedish Academy of Sciences, remarked upon the importance of their discovery [https://www.nobelprize.org/prizes/physics/1902/ceremony-speech/]:

> The greatest credit for the further development of the electromagnetic theory of light

> is due to Professor Lorentz, whose theoretical work on this subject has borne the richest fruit. While Maxwell's theory is free from any assumptions of an atomistic nature, Lorentz starts from the hypothesis that in matter extremely small particles, called electrons, are the carriers of certain specific charges. These electrons move freely in so-called conductors and thus produce an electrical current, whereas in non-conductors their movement is apparent through electrical resistance. Starting from this simple hypothesis, Lorentz has been able not only to explain everything that the older theory explained but, in addition, to overcome some of its greatest shortcomings.
>
> [...] Guided by the electromagnetic theory of light, Zeeman took up Faraday's last experiment, and, after many unsuccessful attempts, finally succeeded in demonstrating that the radiation from a source of light changes its nature under the influence of magnetic forces in such a way that the different spectral lines of which it consisted were resolved into several components. The consequences of this discovery give a magnificent example of the importance of theory to experimental research. Not only was Professor Lorentz, with the aid of his electron theory, able to explain satisfactorily the phenomena discovered by Professor Zeeman, but certain details which had hitherto escaped Professor Zeeman's attention could also be foreseen, and were afterwards confirmed by him. He showed, in fact, that the spectral lines which were split under the influence of magnetism consisted of polarized light, or in other words that the light vibrations are orientated in one particular way under the influence of the magnetic force, and in a way which varies according to the direction of the beam of light in relation to this force.
>
> For the physicist this discovery—the Zeeman effect—represents one of the most important experimental advances that recent decades have to show. For, through the demonstration that light is affected by magnetism in accordance with the same laws as vibrating electrically charged particles, clearly not only has the strongest support been given to the electromagnetic theory of light, but the consequences of Zeeman's discovery promise to yield the most interesting contributions to our knowledge of the constitution of spectra and of the molecular structure of matter. For these reasons the Swedish Royal Academy of Sciences has come to the conclusion that the discovery outlined here is of such great importance for the understanding of the connection between the forces of Nature and for the development of physical science that its recognition by the award of the Nobel Prize for Physics is justified. The Academy also bore in mind the great part which Professor Lorentz has played in the following up of this discovery through his masterly theory of electrons, which is moreover of the greatest significance as a guiding principle in various other realms.

Alfred Landé (German, 1888–1976) later showed that the Zeeman effect was influenced by both the spin and orbital angular momentum of electrons in atoms. A factor in the relevant equations is still known as the Landé g-factor.

Likewise, Johannes Stark (German, 1874–1957) discovered how applied electric fields shift the energy levels of electrons orbiting in atoms, and hence the wavelengths of light that they absorb and emit [Jungnickel and McCormmach 1986]. The specific effects were somewhat different than those induced by magnetic fields, so they provided important new information about the quantum behavior of electrons in atoms. For these experiments, Stark won the Nobel Prize in Physics in 1919. Dr. Å.G. Ekstrand, President of the Royal Swedish Academy of Sciences, announced the award [https://www.nobelprize.org/prizes/physics/1919/ceremony-speech/]:

> Professor Stark. Our Academy of Sciences has awarded you the Nobel Prize in Physics for 1919 in recognition of your epoch-making research into the so-called Doppler effect in canal rays, which has given us an insight into the reality of the internal structure of atoms and molecules. The Nobel Prize relates also to your discovery of the splitting of spectral lines in electric fields—a discovery which is of the greatest scientific importance.

In 1914, James Franck (German, 1882–1964) and Gustav Hertz (German, 1887–1975) carried out an important experiment that became known as the Franck-Hertz experiment [L'Annunziata 2016; Weber 1988]. By colliding electrons of various energies with atoms, they demonstrated that electron orbits in atoms only have certain allowed energy levels, as had already been independently suggested by optical experiments. Both Franck and Hertz went on to make many other important contributions to physics, especially later in nuclear weapons programs (Franck in the United States, Hertz first in Germany and then in the Soviet Union—see Chapter 8). For their famous experiment together, though, they won the Nobel Prize in Physics in 1925. Professor C.W. Oseen, a member of the Nobel Committee for Physics, praised their work [https://www.nobelprize.org/prizes/physics/1925/ceremony-speech/]:

> Franck and Hertz have opened up a new chapter in physics, viz., the theory of collisions of electrons on the one hand, and of atoms, ions, molecules or groups of molecules on the other. This should not be interpreted as meaning that Franck and Hertz were the first to ask what happens when an electron collides with an atom or a molecule, or that they were the originators of the general method which paved the way for their discoveries and which consists of the study of the passage of a stream of electrons through a gas. The pioneer in this field is Lenard. But Franck and Hertz have developed and refined Lenard's method so that it has become a tool for studying the structure of atoms, ions, molecules and groups of molecules. By means of this method and not least through the work of Franck and Hertz themselves, a great deal of material has been obtained concerning collisions between electrons and matter of different types. Although this material is important, even more important at the present time is the general finding that Bohr's hypotheses concerning the different states of the atom and the connexion between these states and radiation, have been shown to agree completely with reality.

As already noted, the Danish physicist Niels Bohr used some of these results to propose one of the first quantum models of how electrons orbit in the atom, and how they can emit or absorb photons of electromagnetic energy by changing from one orbit to another. For that work, he won the Nobel Prize in Physics in 1922 [https://www.nobelprize.org/prizes/physics/1922/ceremony-speech/]. Bohr interacted very closely with the greater German-speaking scientific community throughout his long career, hosting visiting German-speaking scientists in Denmark and visiting German-speaking scientists in their home countries and in the U.S. nuclear laboratories that later employed many of them [Jungnickel and McCormmach 1986; Rhodes 1986].

Bohr's atomic models were expanded and extended by Arnold Sommerfeld (German, 1868–1951) [Eckert 2013]. Sommerfeld patiently worked out the theoretical foundations for much of quantum physics, applying it to everything from individual atoms to metallic solids. As a result, his name is still attached to many key formulas and theories, such as the Sommerfeld model of electrons in metals, the Sommerfeld fine structure constant, the Sommerfeld identity, the Sommerfeld approximation, and many others. He was also famed as a teacher and mentor, authoring physics books that were used worldwide and training a vast number of students in his own lab, many of whom went on to make major discoveries themselves. Historian Michael Eckert summed up Sommerfeld's enormous impact [Eckert 2013, p. XI]:

> Who was Arnold Sommerfeld? Along with Max Planck (1858–1947), Albert Einstein (1879–1955), and Niels Bohr (1885–1962), he belongs among the founders of theoretical physics, which developed into an independent discipline during his lifetime (1868–1951). Among his best known achievements is the elaboration of the Bohr atomic theory established a century ago. Even among physicists of the twenty-first century, the "Bohr-Sommerfeld Atom" and the "Sommerfeld fine-structure constant" remain current concepts. Older physicists associate Sommerfeld's name with the first "school" of modern theoretical physics, and with the work known as the "Bible of atomic physics," *Atomic Structure and Spectral Lines.* This legendary textbook was spread throughout the world in many editions and translations, and initiated generations of physics students into the field of nuclear physics. Additionally, Sommerfeld's *Lectures on Theoretical Physics*, published in six volumes, and reissued long after his death in ever new editions, conveys a sense of the charismatic teacher's personality. At the University of Munich, where he taught and pursued research from 1906 for over three decades, the tradition of the Sommerfeld school continues at the "Arnold Sommerfeld Center for Theoretical Physics." [...] A hundred years ago, the Munich "nursery of theoretical physics" (as Sommerfeld liked to describe his institute) was a haven for the new quantum physics. Sommerfeld's students included Nobel Prize winners Peter Debye (1884–1966), Max von Laue (1879–1960), Wolfgang Pauli (1900–1958), Werner Heisenberg (1901–1976), Linus Pauling (1901–1994) and Hans Bethe (1906–2005). With his 81 nominations, Sommerfeld himself holds the sad record of having been proposed for the Nobel Prize more often than any other physicists . . . without ever receiving the coveted distinction.

5.4.2 Final Development of Quantum Theory

Building on the work of Sommerfeld and other early physicists, much of the overarching framework of what became the final version of quantum theory was provided (at least in large part) by Erwin Schrödinger (Austrian, 1887–1961) [Moore 1989] and Werner Heisenberg (German, 1901–1976) [Cassidy 1992, 2009]. The names of these two physicists remain recognized even by the modern general public:

- "Schrödinger's cat" is a thought experiment involving a cat that is both alive and dead at the same time as the result of an unobserved quantum experiment, in order to emphasize the strangeness of the concept that smeared-out quantum waves can be in two different places or in two different states at the same time.

- The "Heisenberg uncertainty principle" describes how trying to make one aspect of a quantum wave (such as its position) less blurry and more accurately measured inevitably causes other aspects of the wave (such as its momentum) to become even more blurry and less accurately measured.

In the mid-1920s, Schrödinger and Heisenberg independently derived two theories of quantum physics that were fully equivalent to each other, yet expressed in very different mathematical terms.

Schrödinger used wave equations to calculate the smoothly varying back-and-forth wiggling motion of matter waves in space and time. Heisenberg preferred to calculate with matrices of numbers, where each number essentially represented how many humps a matter wave had. Ultimately both mathematical approaches gave the same answer, although Schrödinger's approach made it somewhat easier to solve some problems, and Heisenberg's approach made it somewhat easier to solve other problems.

Since the Nobel Committee for Physics had not awarded a prize in 1932, in 1933 it chose to simultaneously award Heisenberg with the 1932 Nobel Prize and Schrödinger with the 1933 Nobel Prize in Physics. Professor H. Pleijel, Chairman of the Nobel Committee for Physics, described how their discoveries fit together [https://www.nobelprize.org/prizes/physics/1933/ceremony-speech/]:

> Since the electrons were the seat of outgoing waves, Schrödinger thought that it should be possible to find a wave equation for the motions executed by the electrons which would define these waves in the same way as the wave equation which determined the propagation of light. From the solution of this wave equation one should be able to select those oscillations which were feasible for the motions within the atoms. He was successful, too, in determining the wave equation for a series of different motions of the electron, and it turned out that these equations gave finite solutions only when the energy of the system had specific discrete values, determined by Planck's constant. In Bohr's theory these discrete energy values of the electron paths were only hypothetical, but in Schrödinger's, on the contrary, they appeared as completely determined by the form of the wave equation. Schrödinger himself, and others after him, have applied his wave theory to various optical problems including the interpretation of the phenomena accompanying the impact between light rays and electrons, investigations into the behaviour of atoms in electric and magnetic fields, the diffraction of light rays, etc. In every direction, values and formulae have been obtained using Schrödinger's theory, which have been in closer agreement with experience than the older theories were. Schrödinger's wave equation has provided a convenient and simple method for handling problems to do with light spectra, and has become an indispensible tool for the present-day physicist.
>
> Somewhat before the appearance of Schrödinger's theory Heisenberg brought out his famous quantum mechanics. Heisenberg started off from quite different standpoints and viewed his problem, from the very beginning, from so broad an angle that it took care of systems of electrons, atoms, and molecules. According to Heisenberg one must start from such physical quantities as permit of direct observation, and the task consists of finding the laws which link these quantities together. The quantities first of all to be considered are the frequencies and intensities of the lines in the spectra of atoms and molecules. Heisenberg now considered the combination of all the oscillations of such a spectrum as one system, for the mathematical handling of which, he set out certain symbolical rules of calculation. It had formerly been determined already that certain kinds of motions within the atom must be viewed as independent from one another to a certain degree, in the same way that a specific difference is made in classical mechanics between parallel motion and rotational motion. It should be mentioned in this connection that in order to explain the properties of a spectrum it had been necessary to assume self-rotation of the positive nuclei and the electrons. These different kinds of motion for atoms and molecules produce different systems in Heisenberg's quantum mechanics. As

> the fundamental factor of Heisenberg's theory can be put forward the rule set out by him with reference to the relationship between the position coordinate and the velocity of an electron, by which rule Planck's constant is introduced into the quantum-mechanics calculations as a determining factor.
>
> Although Heisenberg's and Schrödinger's theories had different starting points and were developed by the use of different processes of thought, they produced the same results for problems treated by both theories.

What is often overlooked is that Heisenberg did not develop the matrix version of quantum physics alone, but rather with other physicists. One of those was Max Born (German, 1882–1970), Heisenberg's mentor at Göttingen [Greenspan 2005]. Born also made a hugely important contribution to Schrödinger's wave version of quantum physics, by showing that the waves represent the probability of where the corresponding particle could be found. Born made numerous other important contributions to theoretical physics, many of which now bear his name (Born approximation, Born equation, Born series, Born-Haber cycle, Born-Infeld theory, Born-Landé equation, Born-Oppenheimer approximation, Born-von Kármán boundary condition, etc.). Over the course of Born's career, he mentored many students and young scientists. In addition to Heisenberg, they included Max Delbrück, Walter Elsasser, Enrico Fermi, Siegfried Flügge, Maria Goeppert-Mayer, Friedrich Hund, Pascual Jordan, Lothar Nordheim, J. Robert Oppenheimer, and Victor Weisskopf. For his contributions to quantum physics, Max Born won the Nobel Prize in Physics in 1954. Professor I. Waller, a member of the Nobel Committee for Physics, explained the importance of Born's innovations [https://www.nobelprize.org/prizes/physics/1954/ceremony-speech/]:

> Research into the laws valid for the movement of the electrons around the nucleus in the centre of the atom has been a central problem for physics during this century. Niels Bohr made a start on the solution to the problem in 1913. But his theory was of a provisional nature. Professor Max Born took an active part in striving to improve it, as did the many followers who gathered round him in Göttingen. During the twenties of this century, Göttingen, together with Copenhagen and Munich, was a place of pilgrimage for researchers in the field of atomic theory. When the young Heisenberg, formerly a pupil of Sommerfeld in Munich and of Bohr in Copenhagen, published his epoch-making preliminary work on the exact laws for atomic phenomena in 1925, he was Born's assistant in Göttingen. His work was immediately continued by Born, who gave logical mathematical form to the Heisenberg theory. Owing to this progress, Born, in collaboration with his pupil Jordan and later with Heisenberg also, was able to expand the latter's original results into a comprehensive theory for atomic phenomena. This theory was called quantum mechanics.
>
> The following year Born got a new result of fundamental significance. Schrödinger had just then found a new formulation for quantum mechanics. Schrödinger's work expanded the earlier ideas of De Broglie which imply that atomic phenomena are connected with a wave undulation. However, Schrödinger had not solved the problem of how it is possible to make statements about the positions and velocities of particles if one knows the wave corresponding to the particle.
>
> Born provided the solution to the problem. He found that the waves determine the probability of the measuring results. For this reason, according to Born, quantum mechanics

> gives only a statistical description. This can be illustrated by a simple example. When you shoot at a target it is possible in principle—according to the older conception—to aim the shot from the start so that it is certain to hit the target in the middle. Quantum mechanics teaches us to the contrary—that in principle we cannot predict where a single shot will hit the target. But we can achieve this much, that from a large number of shots the average point of impact will lie in the middle of the target. In contradiction to the deterministic predictions of the older mechanics, quantum mechanics accordingly poses laws which are of a statistical character, and as regards single phenomena will only determine the probabilities that one or another of various possibilities will occur. For material bodies of ordinary dimensions the uncertainty of the predictions of quantum mechanics is practically of no significance. But in atomic phenomena, on the other hand, it is fundamental. Such a radical break with older ideas could not of course prevail without opposition. But Born's conception is now generally accepted by physicists, with a few exceptions.
>
> In addition to these achievements, which have been rewarded with the Nobel Prize, Born has made fundamental contributions to many fields of physics. In the first place he dedicated his interest to the theory of crystals and has been one of the great pioneers in that field.

Pascual Jordan (German, 1902–1980) played a major role in the development of both nonrelativistic quantum physics and relativistic quantum physics (Section 5.6) [Jones 2008]. Working directly with Heisenberg and Born, he helped to develop the matrix version of quantum theory. He then went on to publish a string of important papers on quantum theory, both alone and in collaboration with various other physicists. The modern *Encyclopedia Britannica* still includes a brief note testifying to his importance [EB 2010, Jordan, Pascual]:

> German physicist who in the late 1920s founded (with Max Born and Werner Heisenberg) quantum mechanics and (with Wolfgang Pauli and Eugene Wigner) quantum electrodynamics.

Nevertheless, other than a few similarly brief mentions or footnotes in modern books, Jordan's important contributions to the development of quantum physics have been largely forgotten by history, perhaps because of his associations with the German government during World War II. Modern historians should examine Jordan's many scientific accomplishments in much more detail than they generally have.

Paul Ehrenfest (Austrian, 1880–1933) made several important contributions to quantum theory [Jones 2008]. His most famous discovery became known as the Ehrenfest theorem. It described mathematically how, even though quantum waves are very blurry, averages of the waves have the same values as classical mechanics would predict for well-defined particles.

Otto Stern (German, 1888–1969) and Walther Gerlach (German, 1889–1979) demonstrated that the angular momentum of atoms was quantized, or could only have certain values, due to quantum effects [L'Annunziata 2016; Weber 1988]. Their experiment was one of the earliest insights into how quantum physics constrains the behavior of rotating things (angular momentum or spin). For this work, which has since become known as the Stern-Gerlach experiment, Stern won the Nobel Prize in Physics in 1943. Professor E. Hulthén, a member of the Nobel Committee for Physics, described the experiment [https://www.nobelprize.org/prizes/physics/1943/ceremony-speech/]:

> The experiment was carried out in Frankfurt in 1920 by Otto Stern and Walter Gerlach, and was arranged as follows: In a small electrically heated furnace, was bored a tiny hole, through which the vapour flowed into a high vacuum so as to form thereby an extremely thin beam of vapour. The molecules in this so-called atomic or molecular beam all fly forwards in the same direction without any appreciable collisions with one another, and they were registered by means of a detector, the design of which there is unfortunately no time to describe here. On its way between the furnace and the detector the beam is affected by a non-homogeneous magnetic field, so that the atoms—if they really are magnetic—become unlinked in one direction or another, according to the position which their magnetic axles may assume in relation to the field. The classical conception was that the thin and clear-cut beam would consequently expand into a diffuse beam, but in actual fact the opposite proved to be the case. The two experimenters found that the beam divided up into a number of relatively still sharply defined beams, each corresponding to one of the just mentioned discrete positional directions of the atoms in relation to the field. This confirmed the space-quantization hypothesis. Moreover, the experiment rendered it possible to estimate the magnetic factors of the electron, which proved to be in close accord with the universal magnetic unit, the so-called "Bohr's magneton".
>
> When Stern had, so to speak, become his own master, having been appointed Head of the Physical Laboratory at Hamburg in 1923, he was able to devote all his energies to perfecting the molecular beam method. Among many other problems investigated there was a particular one which excited considerable interest.
>
> It had already been realized when studying the fine structure of the spectral lines that the actual nucleus of the atom, like the electron, possesses a rotation of its own, a so-called "spin". Owing to the minute size of the nuclear magnet, estimated to be a couple of thousand times smaller than that of the electron, the spectroscopists could only determine its size by devious ways—and that too only very approximately. The immense interest attaching in this connection to a determination of the magnetic factors of the hydrogen nucleus, the so-called proton, was due to the fact that the proton, together with the recently discovered neutron, forms the basic constituent of all the elements of matter; and if these two kinds of particles were to be regarded, like the electron, as true elementary particles, indivisible and uncompounded, then as far as the proton is concerned, its magnetic factor would be as many times smaller than the electron's as its mass is greater than the electron's, implying that the magnetic factor of the proton must be, in round figures, 1,850 times smaller than the electron's. Naturally then, it aroused great interest when, in 1933, Stern and his colleagues made this determination according to the molecular beam method, it being found that the proton factor was about 2½ times greater than had theoretically been anticipated.

Wolfgang Pauli (Austrian, 1900–1958) explained mathematically how angular momentum or spin works in quantum systems, constructing what are now known as Pauli spin matrices [L'Annunziata 2016; Weber 1988]. Moreover, he proved that identical particles with half-integer spin values that are in the same atom or other quantum system do not want to do the exact same thing as each other, which became known as the Pauli exclusion principle. For example, in an atom, each electron finds a way to orbit or spin somewhat differently than every other electron. The same is also true among the protons in the atomic nucleus, and likewise among the neutrons in the nucleus. Pauli won the

Nobel Prize in Physics in 1945. Professor I. Waller, a member of the Nobel Committee for Physics, praised Pauli's discoveries [https://www.nobelprize.org/prizes/physics/1945/ceremony-speech/]/:

> At this stage of the development of atomic theory, Wolfgang Pauli made a decisive contribution through his discovery in 1925 of a new law of Nature, the exclusion principle or Pauli principle. [...]
>
> The principle, first discovered for electrons, has proved to be valid for the nuclei of hydrogen, called protons, and also for the neutrons which are formed in many nuclear reactions. The neutrons are particles which have no charge but have approximately the same masses as the protons. According to present views any atomic nucleus consists of protons and neutrons. The Pauli principle is therefore essential for the description of the properties of atomic nuclei.
>
> Pauli occupies a leading position in present theoretical physics. He has made many other important contributions to different branches of his science, among them several to nuclear physics.

Friedrich Hund (German, 1896–1997) worked out specifically how the electrons in an atom are arranged in accordance with the Pauli exclusion principle [Laurie Brown et al. 1995]. The patterns he found, now called Hund's rules, are still widely used in atomic physics and chemistry.

Other aspects of quantum theory were named after their originators [Laurie Brown et al. 1995]. Gregor Wentzel (German, 1898–1978), Hendrik Kramers (Dutch, 1894–1952), and Léon Brillouin (French, 1889–1969) independently and roughly simultaneously in 1926 proposed what is now known as the Wentzel-Kramers-Brillouin (WKB) approximation for estimating the size of a quantum matter wave under conditions that are too complicated to find exact mathematical solutions. George Gamow (1904–1968) was Russian but studied and worked in Germany before moving to the United States. In Göttingen in 1928, Gamow used the WKB approximation to calculate the rate at which alpha particles can quantum-mechanically tunnel out of the nucleus, introducing a factor still known as the Gamow factor.

Similarly, Willy Thomas (German?, ??–??), Fritz Reiche (German, 1883–1969), and Werner Kuhn (Swiss, 1899–1963) developed the Thomas-Reiche-Kuhn (TRK) sum rule for calculating transitions rates between different energy levels in atoms or other quantum systems [Laurie Brown et al. 1995]. The WKB and TRK methods of calculating quantum effects remain widely used to this day.

Ralph Kronig (German, 1904–1995) made a number of contributions to quantum theory, including early ideas about electron spin, the Kronig-Penney model of electron behavior in crystals, the Kramers-Kronig relations for optical and electronic properties, and other effects [Laurie Brown et al. 1995].

At least two German-speaking women made important contributions to quantum physics that have been largely overlooked by conventional histories, and there are significant parallels in their careers. Hertha Sponer (German, 1895–1968) received her Ph.D. in physics from the University of Göttingen in 1920 and spent her career doing experimental research on quantum effects (including molecular physics and spectroscopy), first in Germany and then in the United States. In 1946 she married James Franck [https://www.deutsche-biographie.de/sfz123855.html]. Grete Hermann (German, 1901–1984) received her Ph.D. in physics from the University of Göttingen in 1926 and spent her career exploring some of the theoretical and philosophical implications of quantum physics, including whether or not the apparent wave-like nature of matter could be explained away as classical particles simply obeying undiscovered "hidden variables" [https://arxiv.org/abs/0812.3986]. Both Sponer and Hermann left Germany during the Third Reich; Sponor did not return to live in Germany until late in life, whereas Hermann returned soon after the war. Sponer and Hermann, and any other women who played important roles in the development of quantum physics, deserve much more attention than they have received.

Within the German-speaking world, the development of non-relativistic quantum physics had a great impact on many other fields, such as:

Cellular respiration (p. 145).

Vision (p. 281).

Photosynthesis (p. 405).

Inorganic chemistry (p. 427).

Organic chemistry (p. 456).

Physical chemistry (p. 594).

Film Photography (p. 624).

Astrophysics (p. 804).

Statistical/thermal physics (p. 901).

Relativistic quantum physics (p. 923).

Lighting technology (p. 957).

Lasers and holography (p. 1023).

Solid state physics/microelectronics (p. 1034).

Infrared vision (p. 1131).

Electron microscopes (p. 1286).

Nuclear diagnostics/therapeutics (p. 1505).

Radiation detectors (p. 1518).

Models of the atomic nucleus (p. 1530).

Nuclear fission reactions (p. 1537).

Nuclear fusion reactions (p. 1542).

5.5 Statistical and Thermal Physics

Statistical and thermal physics deals with the collective behavior of enormous numbers of particles, such as those that make up solids, liquids, gases, plasmas, and even light or other electromagnetic radiation. Heat or thermal energy is a random jittering of those particles; the higher the temperature, the more the particles dance around. Even though one cannot predict the random motions of any individual particle, the laws of statistical and thermal physics can accurately predict the average behavior of a whole population of particles.

Because statistical and thermal physics deals with collections of microscopic particles, it overlaps with quantum physics, which governs the behavior of particles at the microscopic scale (Section 5.4). Many of the same scientists and discoveries were important for both areas. Yet whereas simple quantum physics only calculates the behavior of one or a few particles, statistical physics employs additional mathematical methods to extend those calculations to huge numbers of particles.

Statistical and thermal physics also describes how such a collection of particles will respond to and carry heat energy in a system such as a refrigerator, an engine, an ice crystal, or a blast furnace. Thus this topic has large degrees of overlap with physical chemistry (Section 3.6), solid state physics (Section 6.5), engineering thermodynamics (Section 7.3), aerodynamics (Section 9.2), and other areas.

According to quantum physics, particles can behave like spinning tops, and the allowed angular momentum of their spin comes in units of $\hbar = h/(2\pi)$, where h is Planck's constant (p. 883). Moreover, some particles have a spin value that is an integer multiple of $\hbar$ (e.g. photons that carry the electromagnetic force and particles that carry the nuclear force have "spin 1," or $1\hbar$), and other particles have a spin value that is a half-integer multiple of $\hbar$ (e.g. electrons, protons, and neutrons have "spin 1/2," or $\hbar/2$). According to statistical and thermal physics, these two categories of particles behave very differently when they are around other particles of the exact same type:

- Integer-spin particles (such as photons) are called "bosons" because they obey Bose-Einstein statistics, which basically means that they are conformists and love to be doing the same thing as each other, unless they have so much thermal energy that they randomly move in many different ways. Since light and other electromagnetic radiation can be viewed as either waves or particles (photons), the boson nature of light is especially important for "black-body radiation," or radiation emitted by something that is so hot that it glows. See Fig. 5.40 for information on how the energy density and spectral distribution of black-body radiation change with the temperature.

- Half-integer-spin particles (such as electrons) are called "fermions" because they obey Fermi-Dirac statistics, which essentially means that they are individualists, with each particle in a system insisting on doing at least one thing differently than any other identical particle in that system (the Pauli exclusion principle). That difference might be having a different energy, different spin direction (e.g., up vs. down), or different magnitude or direction for the angular momentum of the particle's orbit. If a population of fermions has very little thermal energy, they fill up all the lowest available energy states, like sports fans arriving in a stadium with open seating. If a population of fermions has significant thermal energy, some of them randomly jump up to higher energy states, leaving their formerly occupied lower energy states empty (like sports fans who are so excited that they run up and down the levels of the stadium). Figure 5.41 illustrates the characteristics of fermions such as electrons.

As some of the names in the introduction of this section suggest, there were some important contributions to statistical and thermal physics from outside the German-speaking world. The most notable outside contributions came from Satyendra Bose (Indian, 1894–1974), Sadi Carnot (French, 1796–1832), Subrahmanyan Chandrasekhar (Indian, 1910–1995), Paul Dirac (English, 1902–1984), Enrico Fermi (Italian, 1901–1954), James Joule (English, 1818–1889), Lord Kelvin (Scottish, 1824–1907), and James Clerk Maxwell (Scottish, 1831–1879). With the exception of Bose, Chandrasekhar, Dirac, and Fermi, those outside contributions occurred before the German-speaking scientific world had really ramped up by the late nineteenth century.

After that time, a large number of German-speaking physicists dominated the field, as shown in Figs. 5.42–5.47.[6]

For simplicity, the German-speaking creators in this section are divided into the following categories of research:

5.5.1. Thermodynamic properties

5.5.2. Bosons

5.5.3. Fermions

5.5.4. Cryogenics

---

[6] For coverage of different aspects of this area, see especially: Laurie Brown et al. 1995; Gamow 1966; Jones 2008; Jungnickel and McCormmach 1986, 2017; Kragh 2002; L'Annunziata 2016; von Meÿenn 1997; Ingo Müller 2007; Teichmann et al. 2008; Weber 1988.

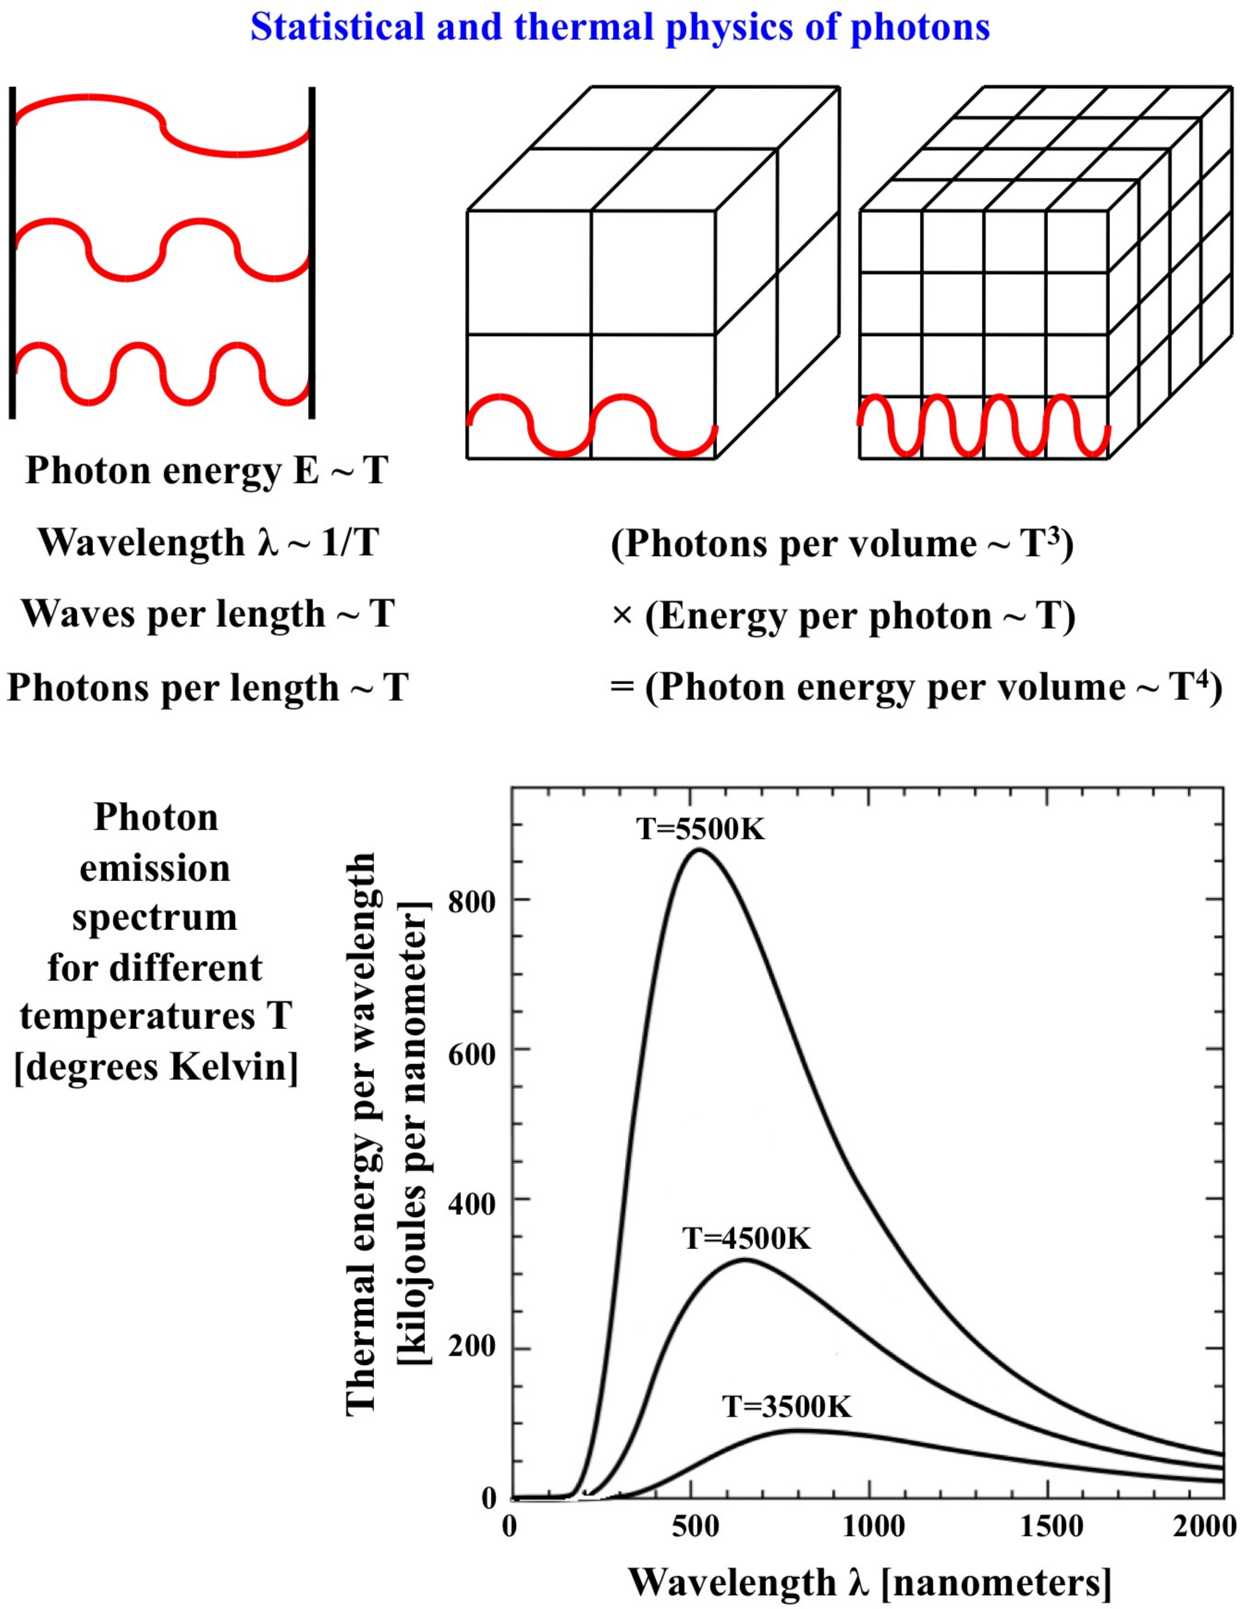

Figure 5.40: Some important discoveries in statistical and thermal physics are that the energy density of photons (electromagnetic radiation such as light) rapidly increases with temperature T (as T^4), and that a hot object emits a spectrum of photons with a predominant wavelength that becomes shorter as the temperature increases.

5.5.1 Thermodynamic Properties

Julius von Mayer (German, 1814–1878) expressed the first law of thermodynamics, the law of conservation of energy (including heat energy and work), in 1841. (James Joule independently rediscovered that law, published it in 1843, and historically has received most of the publicity for it.) He was also the first to find equations for the specific heat of an ideal gas, or the relationship between the amount of heat energy absorbed by a substance and the corresponding temperature rise for that substance.

Hermann von Helmholtz (German, 1821–1894) made a wide variety of major discoveries in biology (pp. 239, 282, 297, 311), chemistry (p. 597), and physics (p. 859) [Cahan 2018]. In 1847, he published a more detailed treatment of the first law of thermodynamics, *Über die Erhaltung der Kraft* (*On the Conservation of Energy*), and also studied the thermodynamics of fluids.

In 1850, Rudolf Clausius (German, 1822–1888) was the first to clearly articulate the second law of thermodynamics, that entropy cannot decrease, or equivalently that heat flows from regions of higher temperature to regions of lower temperature.

Johannes van der Waals (Dutch, 1837–1923) developed detailed thermodynamic equations relating the pressure, density, and temperature of gases and liquids. He won the Nobel Prize in Physics in 1910. Professor O. Montelius, President of the Royal Swedish Academy of Sciences, described his accomplishments [https://www.nobelprize.org/prizes/physics/1910/ceremony-speech/]:

> On the basis of this law of what are known as "corresponding states" for various gases and liquids Van der Waals was able to provide a complete description of the physical state of gases and, more important, of liquids under varying external conditions. He showed how certain regularities can be explained which had earlier been found by empirical means, and he devised a number of new, previously unknown laws for the behaviour of liquids.
>
> It appeared, however, that not all liquids conformed precisely to the simple laws formulated by Van der Waals. A protracted controversy arose around these discrepancies which were ultimately found to be attributable to the molecules in these liquids not all being of the same character; the older Van der Waals laws apply only to liquids of uniform composition. Van der Waals then extended his studies to mixtures of two or more types of molecules and here too he managed to find the laws and these, of course, are more complex than those which apply to substances composed of molecules of a single type. Van der Waals is still occupied with working out the details of this great investigation. [...]
>
> Yet Van der Waals' studies have been of the greatest importance not only for pure research. Modern refrigeration engineering, which is nowadays such a potent factor in our economy and industry, bases its vital methods mainly on Van der Waals' theoretical studies.

Josiah Gibbs (American but educated in Germany, 1839–1903) derived equations for the thermodynamic properties of chemical mixtures, and also showed how to calculate the behavior of substances as collections of large numbers of particles.

Ludwig Boltzmann (Austrian, 1844–1906) developed an extensive framework of statistical physics equations for describing the thermodynamic behavior of large numbers of particles in solids, liquids, or gases [Boltzmann 1964]. As part of that work, he gave a precise mathematical definition of entropy for the second law of thermodynamics.

Wilhelm Ostwald (German, 1853–1932) also developed statistical physics methods that were applicable to thermodynamic processes in both chemistry and physics. Ostwald's work won the Nobel Prize in Chemistry in 1909. Dr. H. Hildebrand, President of the Royal Academy of Sciences, praised Ostwald's discoveries [https://www.nobelprize.org/prizes/chemistry/1909/ceremony-speech/]:

> The Royal Academy of Sciences has resolved to award the former professor at Leipzig University and Geheimrat, Wilhelm Ostwald, the Nobel Prize for Chemistry 1909 in recognition of his work on catalysis and associated fundamental studies on chemical equilibria and rates of reaction. [...]
>
> The significance of this new idea is best revealed by the immensely important role—first pointed out by Ostwald—of catalytic processes in all sectors of chemistry. Catalytic processes are a commonplace occurrence, especially in organic synthesis. Key sections of industry such as e.g. sulphuric acid manufacture, the basis of practically the whole chemical industry, and the manufacture of indigo which has flourished so during the last ten years, are based on the action of catalysts. A factor of perhaps even greater weight, however, is the growing realization that the enzymes, so-called, which are extremely important for the chemical processes within living organisms, act as catalysts and hence the theory of plant and animal metabolism falls essentially in the field of catalyst chemistry. [...]
>
> Although the Nobel Prize for Chemistry is now being awarded to Professor Ostwald in recognition of his work on catalysis, he is a man to whom the chemical world is indebted also in other ways. By the spoken and the written word he, perhaps more than any other, has carried modern theories to a rapid victory and for several decennia he played a leading part in the field of general chemistry. In other ways too he has furthered chemistry by his versatile activity with numerous discoveries and refinements in both the experimental and the theoretical spheres.

Similar to Ostwald, Walther Nernst (German, 1864–1941) made important discoveries regarding the statistical physics underlying thermodynamics, physical chemistry, electrochemistry, and the physics of solids. He won the Nobel Prize in Chemistry in 1920. Professor Gerard de Geer, President of the Royal Swedish Academy of Sciences, announced the award [https://www.nobelprize.org/prizes/chemistry/1920/ceremony-speech/]:

> Herr Geheimrat Nernst. The discovery of fire, which during the classic age was still attributed to a titan, Prometheus, is both the oldest and certainly the most important of all discoveries.
>
> For long years chemists eagerly sought the suspected connection between the evolution

> of heat and the chemical affinity during the combustion of coal and in other chemical reactions.
>
> Your work has now brought this connection to light.
>
> You have used brilliant acuteness during your masterly experimental researches on specific heat and chemical equilibria.
>
> Using the heat theorem discovered by you it has now become possible on the one hand to calculate from the heat evolution during chemical reactions and the specific heats, the chemical affinity and the maximum possible output of energy during chemical reactions, and on the other hand to calculate the equilibrium in reactions not yet studied.
>
> The Academy of Sciences has decided to hand you the Nobel Prize for Chemistry as recognition of the exceptional merit of your work on Thermochemistry.

Peter Debye (Dutch, 1884–1966) studied and worked in Germany and Switzerland for many years. He developed statistical models of the behavior of molecules, chemical solutions, and crystalline solids. For his work, he was honored with the Nobel Prize in Chemistry in 1936. Professor A. Westgren, Secretary of the Nobel Committee for Chemistry, congratulated him [https://www.nobelprize.org/prizes/chemistry/1936/ceremony-speech/]:

> Professor Debye. Your rich scientific activity has been aimed in particular to research into the structure of matter. Your wealth of ideas, your penetration and your secure mastery of mathematical methods have yielded great success to your endeavours, and your results have enriched chemistry to an extraordinary degree in all kinds of ways. By your investigations on dipole moments and also on X-ray and electron interferences in gases you have widened and deepened our knowledge of molecular structure to such an extent that the Royal Academy of Sciences has awarded you the Nobel Prize for Chemistry.

Leo Szilard (Hungarian, 1898–1964) introduced several thermodynamic innovations including the Szilard engine, new ideas about Maxwell's demon, and the Einstein refrigerator.

5.5.2 Bosons

As mentioned in Section 5.4, experimental and theoretical investigations of black-body radiation led directly to the development of quantum physics. Those investigations were also a critical part of statistical and thermal physics, since black-body radiation is an example of the behavior of large numbers of bosons (photons).

Beginning in the 1850s, Gustav Kirchhoff (German, 1824–1887) conducted the first experimental and theoretical investigations of black-body radiation, and was also responsible for giving it that name. Historian of science Ingo Müller described Kirchhoff's foundational role in this area [Müller 2007, p. 199]:

> Kirchhoff conceived of a *black body*, a hypothetical body that sends out radiation of all frequencies and that should therefore—by Kirchhoff's law—also absorb all radiation, and reflect none, so that it appears black. Such black bodies came to play an important role in radiation research, although in the early days no real good black body existed to serve as a reliable object of study. Therefore Kirchhoff suggested an ingenious surrogate in the form of a cavity with blackened, e.g. soot-covered interior walls, which could be heated. Any radiation that enters the cavity by a small hole is absorbed or reflected when it hits a wall. If reflected, the light will most likely travel to another spot of the wall, being absorbed or reflected there, etc. In this way virtually no reflected light comes out through the hole so that the hole itself absorbs radiation *as if it were* a black body. The radiation emitted through the hole is called cavity radiation and it can be studied at leisure for any temperature of the walls.

In 1879, Josef Stefan (Austrian, 1835–1893) experimentally demonstrated that the power of emitted black-body radiation varies as the fourth power of the temperature, as shown at the top of Fig. 5.40. Stefan was also the doctoral advisor for Ludwig Boltzmann, who found a theoretical derivation for that relationship in 1884, so the relationship between power and temperature for thermal radiation is now known as the Stefan-Boltzmann law.

In the late nineteenth century, increasingly accurate experimental measurements of the spectrum of black-body radiation were conducted by Ferdinand Kurlbaum (German, 1857–1927), Otto Lummer (German, 1860–1925), Ernst Pringsheim (German, 1859–1917), Heinrich Rubens (German, 1865–1922), and Wilhelm Wien (German, 1864–1928). Those experiments essentially yielded the curves shown at the bottom of Fig. 5.40 for how the spectrum of black-body radiation varies with changes in the temperature of the object emitting the radiation.

Several scientists worked to develop equations to describe the measured black-body radiation spectrum, as well as physical explanations for the origins of those equations. Wilhelm Wien derived an approximate equation for that spectrum in 1896, and showed that it agreed quite well with his experiments except at very long wavelengths. Friedrich Paschen (German, 1865–1947) independently arrived at the same equation at the same time, although primarily based on experimental data and not theoretical reasons. In 1900, Max Planck (German, 1858–1947) found the exact equation for the black-body radiation spectrum at all wavelengths, and showed that it resulted from light behaving like a collection of particles, or photons.

For their discoveries regarding black-body radiation, Wien won the Nobel Prize in Physics in 1911 and Max Planck won it in 1918 [https://www.nobelprize.org/prizes/physics/1918/ceremony-speech/].

In awarding the 1911 Nobel Prize to Wien, Dr. E. W. Dahlgren, President of the Royal Swedish Academy of Sciences, emphasized the long line of German-speaking scientists who had pioneered the study of black-body radiation [https://www.nobelprize.org/prizes/physics/1911/ceremony-speech/]:

> Ever since the beginning of the last century and, in particular, since spectrum analysis reached an advanced stage of development as a result of the fundamental work by Bunsen and Kirchhoff, the problem of the laws of heat radiation has occupied the attention of physicists to an exceptionally high degree. [...]
>
> The difficulty in investigating the laws of radiation of black bodies was, firstly, that no completely black body exists in nature. In accordance with Kirchhoff's definition, such a body would reflect no light at all, nor allow light to pass. Even substances such as soot, platinum black etc. reflect part of the incident light.
>
> This difficulty was only removed in 1895, when Wien and Lummer stated the principles according to which a completely black body could be constructed, and showed that the radiation which issues from a small hole in a hollow body whose walls have the same temperature behaves in the same manner as the radiation emitted by a completely black body. The principle of this arrangement is based on the views of Kirchhoff and Boltzmann and had already been applied in part by Christiansen in 1884.
>
> With the assistance of this apparatus it now became possible to investigate black body radiation. In this manner, Lummer, together with Pringsheim and Kurlbaum, succeeded in substantiating the so-called Stefan-Boltzmann law which indicates the relationship between the quantity of heat radiated by a black body and its temperature. [...]
>
> In 1893 Wien published a theoretical paper which was destined to acquire the utmost importance in the development of radiation theory. In this paper he presented his so-called displacement law which provides a very simple relationship between the wavelength having the greatest radiation energy and the temperature of the radiating black body.
>
> The importance of Wien's displacement law extends in various directions. As we shall see, it provides one of the conditions which are required for the determination of the relationships between energy radiation, wavelength and temperature for black bodies, and thus represents one of the most important laws in the theory of heat radiation. Wien's displacement law has however acquired the greatest possible importance in other contexts as well. Lummer and Pringsheim have shown that the radiation of bodies other than black bodies obeys the displacement law, with the sole difference that the constant which forms part of the formula has a different value. [...]
>
> It was only natural that Wien who had contributed so much to the advancement of radiation theory should make an attempt to find an answer to the last remaining question also, i.e. that of the distribution of energy in radiation. In 1894 he indeed deduced a black body radiation law. This law has the virtue that, at short wavelengths, it agrees with the above-mentioned experimental investigations by Lummer and Pringsheim. [...]
>
> The problem now became to bridge the gap between these two laws each of which had been shown to be valid in a specific context. It was Planck who solved this problem; as far as we are aware, his formula provides the long sought-after connecting link between radiation energy, wavelength and black body temperature.

Physicist Robert Weber described the scientific contributions of Wien and Planck in more detail [Weber 1988, pp. 43, 58–59]:

> Wien's major work dealt with the distribution of radiant energy in the spectrum and the effect of a change in temperature on this distribution. Wien and Otto Lummer devised the first practical black-body or cavity radiator to provide the 'full radiation' needed for their experiments. [...]
>
> Wien next investigated the problem of the distribution of energy among the wavelengths in black-body radiation. Thermodynamical reasoning was not sufficient. Wien made some arbitrary assumptions (within the framework of classical physics) about the role of molecules in the emission of radiation, and arrived at the formula
>
> $$E_\lambda = \frac{c_1}{\lambda^{-5}\exp(-c_2/\lambda T)} ,$$
>
> where E_λ is the energy at wavelength λ over a unit range of wavelength, and c_1 and c_2 are constants, which he determined by curve-fitting. Wien's formula predicts intensities a little lower than experimental values for large values of λT. The search for a better formula led Max Planck to formulate the quantum theory of radiation. Satisfyingly, Planck's theory gives c_1 and c_2 in terms of fundamental physical constants, but oddly, Planck's equation differs from Wien's in form only by the addition of a (-1) in the denominator. In temperature measurements with an optical pyrometer, Wien's equation is still often used; the calculations are simpler and sufficiently accurate. [...]
>
> Beginning in about 1896 Planck became interested in finding the correct theoretical expression for the radiation from a black body. He applied Boltzmann's equation from the theory of gases (relating entropy and probability) to a set of resonators, the energy of which, he hypothesized, occurred only in *discrete multiples of* ε. From Wien's displacement law he reasoned that the entropy was a function of E/ν (energy/frequency). He was then led (1900) to the famous relation between a quantum of energy and the frequency, and to the introduction of the constant h named after him: $E = h\nu$.
>
> The resulting Planck radiation law, unlike Wien's, fitted all the experimental data [...] Einstein spotlighted attention on Planck's work when he used the concept of quanta in his explanation of the photoelectric effect, in 1905. Next the quantum concept was exploited in the Rutherford-Bohr model of the atom. The fact that it took 25 years of experimental and theoretical work to build the quantum theory is one measure of the quality of Planck's contribution.

In 1905, Albert Einstein (German, 1879–1955) provided detailed theoretical calculations to show that light was also behaving like particles or photons in the photoelectric effect. For that work, he won the Nobel Prize in Physics in 1921 (p. 890). In several papers published over the span of a couple of decades, Einstein extended his initial treatment of photons to cover a population of any identical particles of integer spin. In 1924, Einstein also helped Satyendra Bose to publish a paper that gave an alternative derivation of Planck's earlier equation. As a result, populations of integer-spin particles became known as Bose-Einstein particles, or bosons for short.[7] Historian Walter Isaacson evaluated Einstein's contributions [Isaacson 2007, pp. 98, 328–329]:

> Einstein explored this hypothesis [in 1905] by determining whether a volume of blackbody radiation, which he was now assuming consisted of discrete quanta, might in fact behave like a volume of gas, which he knew consisted of discrete particles. First, he looked at the formulas that showed how the entropy of a gas changes when its volume changes. Then he compared this to how the entropy of blackbody radiation changes as its volume changes. He found that the entropy of the radiation "varies with volume according to the same law as the entropy of an ideal gas."
>
> He did a calculation using Boltzmann's statistical formulas for entropy. The statistical mechanics that described a dilute gas of particles was mathematically the same as that for blackbody radiation. This led Einstein to declare that the radiation "behaves thermodynamically as if it consisted of mutually independent energy quanta." It also provided a way to calculate the energy of a "particle" of light at a particular frequency, which turned out to be in accord with what Planck had found. [...]
>
> Bose's [1924] paper dealt with photons, which have no mass. Einstein extended the idea by treating quantum particles *with mass* as being indistinguishable from one another for statistical purposes in certain cases. "The quanta or molecules are not treated as structures statistically independent of one another," he wrote. [...]
>
> When he applied this approach to a gas of quantum particles, Einstein discovered an amazing property: unlike a gas of classical particles, which will remain a gas unless the particles attract one another, a gas of quantum particles can condense into some kind of liquid even without a force of attraction between them.
>
> This phenomenon, now called Bose-Einstein condensation, was a brilliant and important discovery in quantum mechanics, and Einstein deserves most of the credit for it. [...]
>
> In 1995, Bose-Einstein condensation was finally achieved experimentally by Eric A. Cornell, Wolfgang Ketterle, and Carl E. Wieman, who were awarded the 2001 Nobel Prize for this work.

---

[7] In retrospect, it seems odd that of all the scientists who worked on this topic, it was Bose who was immortalized when this category of particles was named. His 1924 paper arrived at the same result that Max Planck had nearly a quarter century earlier, it was only published with Einstein's input and assistance, and his other papers before and after that time were undistinguished (especially when compared with those of other Indian physicists and mathematicians such as Homi Bhabha, Subrahmanyan Chandrasekhar, C. V. Raman, and Srinivasa Ramanujan). The mathematical theory describing populations of photons or similar types of particles was progressively developed by Wien, Planck, and Einstein, based on experimental data and earlier work by the other German-speaking scientists going back to Kirchhoff. Perhaps in the aftermath of World War I, when English was the predominant language worldwide and German speakers were isolated and viewed with hostility because of the war, it was easier for the English-speaking world to give name credit to Bose, who was an English-speaking member of the British Empire, than to the series of German-speaking scientists who spent nearly three-quarters of a century developing this part of physics from beginning to end.

5.5.3 Fermions

The greater German-speaking world also dominated in discovering the behavior of fermions such as electrons. The largest and most important parts of this work were conducted by Wolfgang Pauli (Austrian, 1900–1958). In 1924, he realized that each electron in a system such as an atom refused to be in exactly the same state as any other electron in that system, a rule that became known as the Pauli exclusion principle. In 1925, Pauli further realized that data from atomic measurements showed that each state could actually have up to two electrons; he therefore proposed that there was some previously unknown, binary quantum property that was different between those two electrons, so that they would still satisfy the Pauli exclusion principle.

Pauli's new binary-valued property of electrons turned out to be their spin angular momentum, which could be pointed in two distinct directions (e.g., up or down). Ralph Kronig (German, 1904–1995) first proposed the concept of electron spin to Pauli in January 1925. Later in 1925, Paul Ehrenfest (Austrian, 1880–1933) and his students George Uhlenbeck (Dutch, 1900–1988) and Samuel Goudsmit (Dutch, 1902–1978) rediscovered the concept of spin. Ehrenfest also collaborated on statistical physics research with his wife, Tatjana Ehrenfest-Afanassjewa (1876–1964), who was Ukrainian but was educated in Germany and worked in Germany and the Netherlands.

Pauli went on to prove that particles with half-integer spins (such as electrons, protons, and neutrons) behaved as fermions and followed the Pauli exclusion principle with regard to other identical particles in the same system. Moreover, he proved that particles with integer spins (such as photons and mesons) behaved as bosons and actually liked being in the same state as each other when their energies were low enough. In 1927, Pauli also developed what are now known as the Pauli spin matrices, which mathematically describe how the spin states of particles can change (for example, how an electron might change its spin from up to down). For his decisive contributions to this topic, Pauli won the Nobel Prize in Physics in 1945. Physicist Robert Weber [Weber 1988, pp. 125–126] summarized Pauli's discoveries:

> In 1924 Pauli enunciated his 'exclusion principle' with which much of the then existing knowledge of atomic structure fell into order: no two electrons in an atom can be in the same quantum state. In 1925 Pauli wrote that a new quantum theory property of the electron, which he called a 'two-valuedness not describable classically,' was indispensable to an understanding of the anomalous Zeeman effect. Goudsmit and Uhlenbeck identified this fourth quantum number with an angular momentum (spin) of the electron. The exclusion principle could then be stated: no two electrons in an atom can have the same set of four quantum numbers. In this form, Pauli's principle led to an understanding of the formation of electron shells in an atom and the periodicity of chemical properties observed when the elements are arranged in order of increasing atomic number. [...]
>
> Other research papers by Pauli dealt with the relation of quantum spin and the appropriate distribution statistics for elementary particles, paramagnetic properties of gases and of metals (leading to the quantum mechanical theory of electrons in metals), extension of wave mechanics from one to a large number of particles, explanation of the meson, and the nuclear binding force. To explain the beta-decay of radioactive nuclei, Pauli in 1931 postulated the existence of a new subatomic particle; it was named the *neutrino* by Fermi in 1932, and was detected in 1956.

As soon as Pauli published his 1924–1925 papers on the exclusion principle for electrons, Pascual Jordan (German, 1902–1980) realized that that principle could be extended to describe the behavior of very large numbers of electrons (or other particles that behaved in a similar fashion). In 1925, Jordan wrote an elegant paper that derived what is now known as the Fermi-Dirac distribution for such particles, as shown at the bottom of Fig. 5.41. He submitted the paper to Max Born for prompt publication in the widely read physics journal that Born edited, *Zeitschrift für Physik*. Then something unfortunate happened, as recounted by historian Nancy Thorndike Greenspan [Greenspan 2005, p. 135]:

> Born had one disconcerting moment after returning [in 1926]—his discovery of a paper by Pascual Jordan at the bottom of his suitcase. Just before Born's departure [in 1925], Jordan had given it to him for possible publication in the journal *Zeitschrift für Physik*, of which Born was an editor. Born had packed it, intending to read it on the trip. When he pulled it out and finally read it, he saw that Jordan had discovered the important statistical laws that Enrico Fermi had just published in the *Zeitschrift für Physik*. Shortly, Paul Dirac made the same discovery of what became known as the *Fermi-Dirac statistics*. These laws describe the statistical distribution of identical particles of spin ½ (now called *fermions*). They follow Pauli's exclusion principle: that only one such particle can occupy an energy state at a time. These laws, as applied to electrons, aided in the development of the field of electronics. Amid the serious problems that rocked his future relationship with Jordan, Born always felt guilty, even "ashamed," that he had robbed Jordan of his due.

Sadly, it does not appear that journal editor Born made any attempt to rectify or publicly clarify the situation even after the fact. Thus the sequence of events is: Pauli worked out the behavior of small numbers of fermions in 1924–1925. Jordan extended Pauli's results to cover large numbers of fermions in 1925 and submitted his discovery for publication. After perusing Pauli's publications, Enrico Fermi (Italian, 1901–1954) independently rediscovered the same results as Jordan in 1926, and Paul Dirac (English, 1902–1984) rediscovered those same results again in 1927. Yet Jordan has been nearly forgotten by history, and the names of Fermi and Dirac will be forever linked to this topic.[8]

In 1927, Friedrich Hund (German, 1896–1997) used the Pauli exclusion principle to work out the detailed order in which electrons fill progressively higher energy states in atoms that have many electrons. His rules are still widely used today in chemistry and physics.

Also in 1927, Arnold Sommerfeld (German, 1868–1951) used the Pauli exclusion principle to describe the behavior of electrons in metals. Sommerfeld's theory successfully explained the contributions of electrons to the electrical and thermal conductivities of metals, and it is now known as the Sommerfeld or Drude-Sommerfeld model of free electrons. (For Paul Drude's earlier work, see p. 861).

Some other German-speaking scientists who made important contributions to the physics of fermions included Richard Becker (German, 1887–1955) and Markus Fierz (Swiss, 1912–2006).

---

[8] Jordan's virtual omission from this part of history is certainly not the fault of Fermi and Dirac. If Jordan had not existed, Fermi and Dirac would indeed have been the first discoverers of this statistical distribution of particles. Both Fermi and Dirac made a long string of revolutionary discoveries before and after that time. For unrelated work, Dirac won the Nobel Prize in Physics in 1933, and Fermi won it in 1938. Although Fermi came out of the Italian system and Dirac out of the British system, both were highly individualistic geniuses whose accomplishments appear to have been due to their self-created natures and specific circumstances far more than the particular systems in which they lived. Both Fermi and Dirac had extensive interactions with the German-speaking scientific world during their careers. Books have been written about both of them, but their lives should be scrutinized in even more detail for lessons that future scientists might learn.

5.5.4 Cryogenics

Cryogenics concerns methods of producing extremely cold temperatures, very close to absolute zero, and also covers testing the properties of materials at those low temperatures. Many scientists from the greater German-speaking world made tremendously important contributions to cryogenics.

Carl von Linde (German, 1842–1934) greatly improved earlier attempts at ammonia refrigeration to create a truly practical and efficient large refrigeration system. He used that to liquefy air and various gases on an industrial scale.

Zygmunt Wróblewski (Polish, educated in Germany, 1845–1888) and Karol Olszewski (Polish, 1846–1915) also conducted important early work on liquefying different gases and studying their properties.

Raoul Pictet (Swiss, 1846–1929) was the first to produce liquid nitrogen.

Heike Kamerlingh Onnes (Dutch, educated in Germany, 1853–1926) built upon and extended that earlier work, reaching colder and colder temperatures. Using those extremely cold temperatures, he was the first to liquefy helium, and he also discovered superconductivity. For his discoveries, he won the Nobel Prize in Physics in 1913. Th. Nordstrom, President of the Royal Swedish Academy of Sciences, explained the importance of his contributions [https://www.nobelprize.org/prizes/physics/1913/ceremony-speech/]:

> It was for this research that Kamerlingh Onnes set up his famous laboratory at the beginning of the 1880's, and in it he designed and improved, with unusual success, the physical apparatus needed for his experiments.
>
> It is impossible to report briefly here on the many important results of this work. They embrace the thermodynamic properties at low temperatures of a series of monatomic and diatomic gases and their mixtures, and have contributed to the development of modern thermodynamics and to an elucidation of those associated phenomena which are so difficult to explain. They have also made very important contributions to our knowledge of the structure of matter and of phenomena related to it. [...]
>
> I should have to cover too much ground if I were to report here on the experimental equipment with which Kamerlingh Onnes was at last successful in liquefying helium, and on the enormous experimental difficulties which had to be overcome. I would only mention here that the liquefaction of helium represented a continuation of the long series of investigations into the properties of gases and liquids at low temperatures which Kamerlingh Onnes has carried out in so praiseworthy a manner. These investigations finally led to the determination of the so-called isotherms of helium and the knowledge gained here was the first step towards the liquefaction of helium. Kamerlingh Onnes has constructed cold baths with liquid helium which permit research to be done into the properties of substances at temperatures which lie between 4.3^o and 1.15^o from absolute zero.
>
> The attainment of these low temperatures is of the greatest importance to physics research, for at these temperatures both the properties of the substances and also the

> course followed by physical phenomena, are generally quite different from those at our normal and higher temperatures, and a knowledge of these changes is of fundamental importance in answering many of the questions of modern physics. [...]
>
> Various principles borrowed from gas thermodynamics have been transferred to the so-called theory of electrons, which is the guiding principle in physics in explaining all electrical, magnetic, optical, and many heat phenomena.
>
> The laws which have been arrived at in this way also seem to be confirmed by measurements at our normal and higher temperatures. That the situation is at very low temperatures not the same, however, has, amongst other things, been shown by Kamerlingh Onnes' experiments on resistance to electrical conduction at helium temperatures and by the determinations which Nernst and his students have carried out in relation to specific heat at liquid temperatures.

Physicist Anthony J. Leggett indicated how advanced Onnes's achievements were [Laurie Brown et al. 1995, p. 913]:

> If the subject which we now know as low-temperature physics can be said to have a birthday, that day would be 10 July 1908—the date on which Heike Kamerlingh Onnes and his team at the University of Leiden first successfully cooled the element helium (^{4}He) below 4.2 K and thereby liquefied it. For the next 15 years, the only place in the world where liquid helium existed was the Leiden laboratory (now named after Onnes).

Franz Simon (German, 1893–1956) and Nicholas Kurti (Hungarian, 1908–1998) developed refrigerators capable of cooling down to one millionth of a degree Celsius above absolute zero.

Kurt Mendelssohn (German, 1906–1980) studied the properties of liquid helium, demonstrating superfluidity, or flow without any viscosity or friction. He also further investigated the properties of superconductors.

Some other German-speaking scientists who made especially important contributions to superconductivity included Fritz Walther Meissner (German, 1882–1974), Max von Laue (German, 1879–1960), and the brothers Fritz London (German, 1900–1954) and Heinz London (German, 1907–1970). For more information on superconductivity, see p. 1112.

Many of these creators personally transferred their knowledge of advanced cryogenics out of the German-speaking world, as described by Leggett [Laurie Brown et al. 1995, p. 920]:

> By this time political events in Europe had begun to affect the course of low-temperature physics. Following the accession to power of the Nazi government in Germany, the years 1933–34 saw the exodus of many Jewish physicists, including Kurt Mendelssohn, Franz Simon, Nicholas Kurti and the London brothers, all of whom were attracted to Oxford by F A Lindemann (later Lord Cherwell) at the Clarendon Laboratory, which thereby rapidly became a major centre in experimental low-temperature physics. At the same time superconductivity at the PTR suffered a severe blow when Meissner left for Munich and von Laue was fired by the new Nazi-appointed head.

5.6 Relativistic Quantum Physics or Particle Physics

Relativistic quantum field theory (often simply called field theory, for short) combines special relativity, which describes very fast things, and (non-relativistic) quantum physics, which describes very small things. The resulting theory correctly predicts the behavior of fundamental particles, which are small and often move at high speeds, or are in tightly bound states where they rattle around at high speeds. For that reason, the topic is also often called particle physics, as it describes the behavior of particles that are collided together and new particles that are produced in large particle accelerators. Moreover, for the same reason, relativistic quantum theory is the best way to describe the effects of the fundamental physical forces: electromagnetic force, the strong and weak nuclear forces, and gravitational force (as well as real or potential interactions among those forces).

Relativistic quantum field theories describing the fundamental forces other than gravity do not need to incorporate general relativity. They are covered in Section 5.6.1.

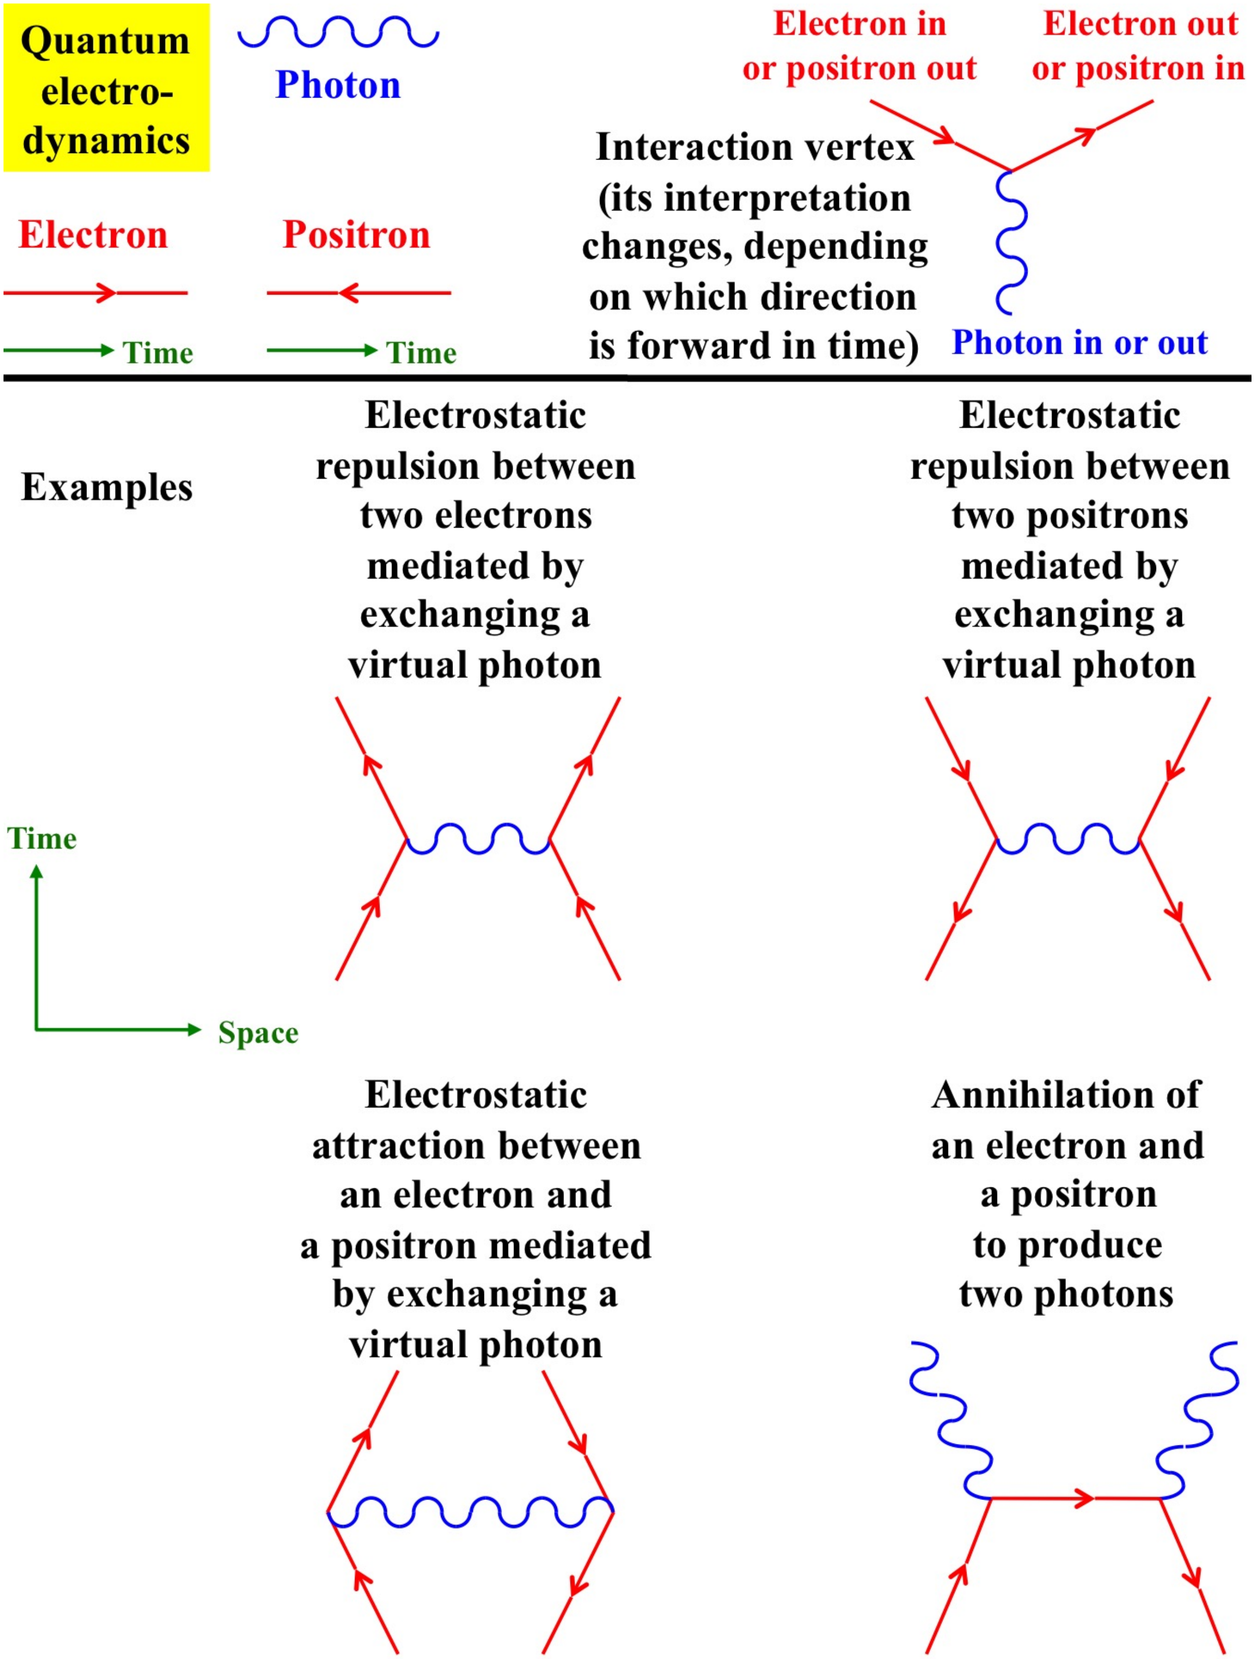
However, relativistic quantum field theories describing gravity (often called quantum gravity for short) do need to incorporate general relativity, and therefore they are significantly more complicated. They are briefly treated in Section 5.6.2.

5.6.1 Quantum Field Theories of Fundamental Forces Other Than Gravity

Relativistic quantum theory applied to the electromagnetic force is called quantum electrodynamics (QED). As shown in Fig. 5.49, one may use QED to picture electrically charged particles such as electrons interacting with photons, the particles that make up an electromagnetic field. One of the first predictions of QED is that normal particles have antimatter versions or antiparticles, which have the opposite charge from the normal particles, or alternately have the same charge but travel backward in time relative to the normal particles. For example, the antimatter version of the negatively charged electron is called a positron, since it has a positive electric charge. A particle-antiparticle pair can be created from electromagnetic energy, or a particle-antiparticle pair can annihilate with each other and produce electromagnetic energy. QED correctly predicts electrostatic repulsion and attraction, particle-antiparticle annihilation, and a number of more complicated effects.

Relativistic quantum theory applied to the weak nuclear force describes phenomena such as the decay of neutrons (beta decay) and muons. Relativistic quantum theory applied to the strong nuclear force is called quantum chromodynamics, and is relevant to the behavior of the quarks that compose particles like protons, neutrons, and pions, as well as the collective interactions among protons, neutrons, and pions that hold the atomic nucleus together.

Relativistic quantum physics and particle physics are generally viewed as subjects that were developed largely after World War II, and largely outside the German-speaking world. The best-known luminaries in the field were mostly Americans (e.g., Richard Feynman, Murray Gell-Mann, Sheldon Glashow, Willis Lamb, Julian Schwinger, and Steven Weinberg) plus a few British (e.g., Paul Dirac and Freeman Dyson) and Japanese physicists (e.g., Sin-Itiro Tomonaga and Hideki Yukawa). Most of the early giant particle accelerators used to experimentally confirm the predictions of relativistic quantum theory were in the United States.



Quantum electro-dynamics

Electrostatic attraction between an electron and a positron mediated by exchanging a virtual photon
Annihilation of an electron and a positron to produce two photons

Figure 5.49: Combining special relativity, quantum physics, and electromagnetism yields quantum electrodynamics, which successfully predicted the existence of antimatter and numerous other effects.

In fact, there were a large number of German-speaking scientists who made major early contributions to relativistic quantum theory, as shown in Figs. 5.50–5.54.[9] Their research was foundational to later work outside the German-speaking world, and in some cases they made the same discoveries as non-German-speaking scientists, but earlier (and sadly with far less fame). There are several reasons why there was not even more German-speaking work on relativistic quantum theory, and why the work that was conducted is not as well known as it should be:

- The most detailed, successful work on combining relativity with non-relativistic quantum theory could not begin until non-relativistic quantum theory was fully developed, which did not occur until the end of the 1920s. Very soon thereafter, the rise of Nazism caused ~25% of scientists (including many of those working on relativistic quantum theory) to leave German-speaking Europe, disrupting their work and their interactions with other German-speaking scientists and/or spreading more of the development of relativistic quantum theory to other countries (especially the United States).

- Further development of relativistic quantum theory by scientists who remained in Germany and Austria during the Third Reich was hindered by the Nazi party's dislike for "Jewish physics" theories, the wartime focus on research with military applications, the difficulties of publishing scientific papers during the war and in the first several years after the war, and the scarcity of particle accelerators to confirm theoretical predictions. (The Third Reich appears to have possessed many particle accelerators by the end of the war, but they were devoted to military applications such as nuclear physics during the war, and most were confiscated by Allied countries after the war—see Section C.1 and pp. 3954–4022 and 4504–4510.)

- Likewise, immediate development of relativistic quantum theory by German-speaking scientists who fled to Allied countries was also retarded by the wartime focus on military research and the lack of particle accelerators not devoted to military purposes.

- Further work on relativistic quantum theory after the war in the German-speaking world was greatly impeded by the Allied procurement of most of the scientists, scientific documents, and scientific equipment from the German-speaking world at the end of the war. That chaotic dismantlement of the German-speaking scientific world also obscured many of the scientific results that it had achieved in the preceding years.

- Many of the Americans who contributed to relativistic quantum theory (Murray Gell-Mann, Julian Schwinger, Steven Weinberg, etc.) were the children of immigrants who had fled German-speaking areas of Europe due to the political turmoil of World War I, its aftermath, and the rise of Nazism.

- There are few books that cover the history of relativistic quantum physics, and most of those that do exist were generally written for American and British audiences, without devoting sufficient attention to German-speaking contributions in this field.

---

[9] Most references that focus on relativistic quantum theory tend to provide far too little information on the German-speaking world, while references that do consider the German-speaking world in detail generally focus much more on non-relativistic than relativistic quantum theory. References with at least some information on this topic include: Laurie Brown et al. 1995; Laurie Brown and Hoddeson 1983; Cassidy 1992, 2009; Gamow 1966; Greiner and Reinhardt 1994; Jones 2008; Kragh 2002; L'Annunziata 2016; von Meÿenn 1997; Moore 1989; Schweber 1994; Weber 1988. Blum and Rickles 2018 is wonderful but focuses primarily on quantum gravity and not other parts of relativistic quantum theory in the German-speaking world. Historians of science should write more books in this area!

Gregor Wentzel (1898–1978)

Hermann Weyl (1885–1955)

Eugene Wigner (1902–1995)

Figure 5.56: Other creators who made significant contributions to relativistic quantum physics included Gregor Wentzel, Hermann Weyl, and Eugene Wigner.

Physicist and historian Alexander Blum made it clear that relativistic quantum theory came out of the same German-speaking world that had just produced non-relativistic quantum theory, and that it was founded by many of the same physicists, including Max Born, Werner Heisenberg, Pascual Jordan, Wolfgang Pauli, and Erwin Schrödinger [Blum and Rickles 2018, pp. 49, 255]:

> In the years 1925 to 1927, the old quantum theory was replaced by the newly developed theory of quantum mechanics, which grew out of the matrix mechanics of Heisenberg, Born, and Jordan and the wave mechanics of Schrödinger. Both of these theories were initially formulated entirely non-relativistically. But it was clear from the outset that contact would have to be made with the special theory of relativity for two important reasons: On the one hand, the mechanics would have to be complemented with a quantum electrodynamics (QED), in order to describe the emission and absorption of radiation, as well as the particulate properties of light itself, which by this time (in the wake of the discovery and interpretation of the Compton effect) was a generally accepted fact. On the other hand, the mechanics itself would have to be made relativistic, as it was known, already since the mid 1910s, that relativistic corrections to the kinematics of the electron would have a measurable effect in the fine structure of atomic spectra.
>
> It was Schrödinger's wave mechanics, rather than matrix mechanics, that provided the ideal starting point for a relativistic kinematics of matter: One needed to find a new, relativistic matter wave equation, but at first glance there were no immediate other conceptual difficulties, such as the problem of a non-commuting time variable in matrix mechanics. Schrödinger himself had initially attempted to find a relativistic wave equation, following de Broglie's program of matter waves, which had been formulated in a relativistic manner. But de Broglie had stopped short of addressing the dynamical equations. Schrödinger in fact arrived at the Klein Gordon equation, but he dismissed it, due to its empirical inadequacy (later understood as the absence of spin in the Klein Gordon equation). Others were not as scrupulous, and the Klein Gordon equation was rediscovered (and published) multiple times in the immediate aftermath of Schrödinger's first papers on wave mechanics. [...]
>
> In the years 1926–1928, immediately following the creation of matrix and wave mechanics, the protagonists of this development elaborated and expanded the techniques of the new quantum mechanics, so as to apply them to field theories. This work culminated in the theory of interacting quantum electrodynamics (QED), published in 1929 by Werner Heisenberg and Wolfgang Pauli.

As Blum noted, Schrödinger derived the Klein-Gordon relativistic quantum wave equation for spinless particles years before Klein and Gordon. Schrödinger also worked on quantum gravity, and made numerous other contributions to relativistic quantum field theory [Moore 1989; Weber 1988, pp. 99–100]. Walter Gordon (German, 1893–1939) and Oskar Klein (Swedish but closely coupled to the German-speaking scientific world, 1894–1977) were also part of the same German-speaking physics community.

Historian of science David Cassidy confirmed the foundational roles of German-speaking scientists such as Heisenberg, Jordan, and Pauli in relativistic quantum field theory [Cassidy 1992, p. 276]:

> Since electromagnetic radiation is a manifestation of electric and magnetic fields, the search began almost immediately for what is now called a relativistic quantum field the-

> ory. This extremely technical and mathematical branch of quantum physics, the foundations of which were laid by Heisenberg, Dirac, Pauli, Jordan, and their colleagues during the late 1920s and early 1930s, continues to this day with much the same program and approach. [...] The enormous high-energy accelerators, bubble chambers, and data analysis equipment that were built after World War II, employing vast teams of physicists, technicians, and students, are technological wonders in themselves. They were stimulated by the discovery of new types of nonelectromagnetic fields in the middle 1930s, the quantum behavior of which comes into play only when particles smash into each other at such extremely high energies that their internal workings become evident.
>
> Large-scale experimental research was paralleled by the continuing search for a unified field theory—a quantum field theory encompassing all four types of fields known today, rather than just the electromagnetic field. [...] Werner Heisenberg was again a leading member of the small band of abstract theorists who established the program and laid the foundations of relativistic quantum field theory as it has been pursued ever since.

Physicist Silvan Schweber further described Pauli's contributions to relativistic quantum physics [Schweber 1994, p. 583]:

> Quantum electrodynamics and quantum field theory became Pauli's main concern after 1927. [...] Pauli and Heisenberg formulated the canonical approach to the quantization of field systems in 1929. During the thirties many of the seminal papers in quantum field theory were either written by Pauli, had Pauli as one of its authors, or were written under the acknowledged guidance of Pauli. [...]
>
> Pauli spent the war years, from 1940 to 1946, at the Institute of Advanced Study in Princeton. Most of his efforts during that period were devoted to meson theory.

Felix Villars (Swiss, 1921–2002) collaborated with Pauli on what is now called Pauli-Villars regularization, a mathematical technique of getting physically sensible results (instead of mathematically infinite answers) from relativistic quantum calculations.

J. Robert Oppenheimer (1904–1967) was born in New York but had a German father and second-generation German-American mother, was raised speaking German, repeatedly visited family in Germany during his childhood, and received his Ph.D. under Max Born in Germany. He began working in relativistic quantum theory under Born and Pauli, and continued to work in that field in the United States.

Gregor Wentzel (German, 1898–1978) also began relativistic quantum research with Pauli and then continued in the United States.

Some physicists from the greater German-speaking world won Nobel Prizes related to relativistic quantum theory. Born, Heisenberg, Pauli, and Schrödinger won Nobel Prizes, although those were primarily for their earlier work on non-relativistic quantum physics. Peter Debye (Dutch, 1884–1966) won a Nobel Prize in Chemistry in 1936, yet he also made unrelated contributions to relativistic quantum theory (p. 914). Hans Bethe (German, 1906–2005) also made a number of important contributions to relativistic quantum theory, but his Nobel Prize was for unrelated work on nuclear fusion in stars (p. 1542). Similarly, Felix Bloch (Swiss, 1905–1983) won a Nobel Prize in Physics in 1952, but that was for his research on nuclear magnetic resonance, not his research on relativistic quantum theory (p. 1516). Eugene Wigner (Hungarian, 1902–1995) won a Nobel Prize in Physics in 1963 for his work on mathematical groups and symmetries in physics, which was highly applicable to both nuclear physics and relativistic quantum physics (p. 1535).

Polykarp Kusch (German, 1911–1993) won a Nobel Prize in Physics in 1955 for his contributions to quantum electrodynamics. Professor I. Wailer of the Nobel Committee for Physics explained Kusch's work [https://www.nobelprize.org/prizes/physics/1955/ceremony-speech/]:

> The discovery of Kusch refers directly to an important property of the electron, namely its magnetic moment. It had been known since long that the electron is a small magnet. The strength of this magnet is measured by its moment. The magnitude of the moment should be uniquely determined by the electron theory of Dirac, mentioned before. [...]
>
> Starting from this idea Kusch made a series of very careful investigations and found in 1947 that the magnetic moment of the electron is larger than the Bohr magneton by about one part in a thousand.

In 1936, Walter Heitler (German, 1904–1981) published the first complete textbook on quantum electrodynamics, *The Quantum Theory of Radiation*, which was so farsighted and useful that it is still in print.

Ernst Stückelberg (Swiss, 1905–1984) was one of the German-speaking scientists who made some of the most advanced and yet some of the most historically overlooked contributions to relativistic quantum field theory. He was the first to produce many of the major innovations and solutions in QED for which Richard Feynman later became famous, and he also made revolutionary suggestions regarding the nuclear strong force and other topics in relativistic quantum theory. Physicists Walter Greiner and Joachim Reinhardt gave a very short description of his work [Greiner and Reinhardt 1994, pp. 37–38]:

> Stückelberg [...] made pioneering contributions to quantum field theory. In 1942 he first conceived the idea that positrons can be interpreted as electrons running backward in time. The use of the causal propagator for calculating the scattering matrix was introduced in 1949 independently by R. Feynman and S. [Stückelberg] (with his student D. Rivier). Later S. (with A. Petermann) developed the idea of the renormalization group.

Markus Fierz (Swiss, 1912–2006) studied under and collaborated with Pauli, scrutinized the ideas of Stückelberg, and made a long and extremely fruitful research career of his own in quantum electrodynamics and other areas of relativistic quantum theory. Like Stückelberg, Fierz's many contributions have often been overlooked by those outside the German-speaking world.

Greiner and Reinhardt also mentioned some other German-speaking scientists who made important contributions to relativistic quantum theory. Those included: Max Delbrück (German, 1906–1981), who was much better known for his work on DNA and viruses (pp. 103 and 200); Hans Euler (German, 1909–1941), who obtained his Ph.D. in physics under Werner Heisenberg in 1935 and began a very promising career in quantum field theory that ended with his death during the war; and Victor Weisskopf (Austrian, 1908–2002), who worked in many areas of quantum field theory [Greiner and Reinhardt 1994, p. 381]:

> Delbrück [...] published a short addendum to an experimental paper on the coherent scattering of hard γ rays where he pointed out the possible interaction of photons with

> the vacuum polarization charge induced by a nucleus. The existence of this effect was demonstrated much later and called Delbrück scattering by H. Bethe. [...]
>
> Euler [...] The airplane in which he served as a meteorological observer was shot down in 1941. In his PhD thesis E. [Euler] calculated the QED process of scattering light by light. Subsequently he worked on the theory of high-energy cosmic ray collisions.
>
> Weisskopf [...] In 1934 W. [Weisskopf] formulated a relativistically covariant quantum field theory of bosons (with W. Pauli) and in 1936 introduced concepts which led to renormalization theory.

In 1923, Adolf Smekal (Austrian, 1895–1959) predicted one of the first QED effects, inelastic scattering of photons. That effect was demonstrated several years later by C. V. Raman, who won a Nobel Prize for it.

In 1947, Hendrik Casimir (Dutch, 1909–2000) and Dirk Polder (Dutch, 1919–2001) predicted the Casimir effect, a minute but real force exerted on electrically conductive objects by particles that quantum-mechanically appear out of nothingness and immediately disappear back into nothingness. This effect was actually demonstrated in the 1990s.

Some other physicists who made various early contributions to relativistic quantum theory in the German-speaking world included Richard Becker (German, 1887–1955), Fritz Bopp (German, 1909–1987), Herbert Fröhlich (German, 1905–1991), Nicholas Kemmer (Russian but educated and worked in Germany and Switzerland, lived 1911–1998), and Léon Rosenfeld (Belgian but worked in Germany and Switzerland, lived 1904–1974).

For completeness, some later contributions should also be mentioned. Martinus Veltman (Dutch, 1931–) and Gerard ’t Hooft (Dutch, 1946–) developed the electroweak theory that showed how the electromagnetic force and the weak nuclear force are two different aspects of the same theory. For that insight, they won the Nobel Prize in Physics in 1999. The Royal Swedish Academy of Sciences summarized their research [https://www.nobelprize.org/prizes/physics/1999/veltman/facts/]:

> According to modern physics, four fundamental forces exist in nature. Electromagnetic interaction is one of these. The weak interaction—responsible, for example, for the beta decay of nuclei—is another. In the 1960s, a unified theory was formulated for these two forces: the electroweak interaction. However, certain problems still remained to be solved. In the early 1970s, Martinus Veltman and Gerardus t’Hooft formulated and tested a mathematical theory that further explained the electroweak interaction.

In closely related work, Simon van der Meer (Dutch, 1925–2011) made improvements to particle accelerators that allowed electroweak theory to be confirmed experimentally. He won the Nobel Prize in Physics in 1984. The Royal Swedish Academy of Sciences noted [https://www.nobelprize.org/prizes/physics/1984/meer/facts/]:

> According to modern physics, there are four fundamental forces in nature. The weak interaction, responsible for e.g. the beta-decay of nuclei is one of them. According to the theory forces are mediated by particles: the weak interaction by the so called heavy bosons W, Z, about 100 times more massive than the proton. Simon van der Meer developed a method to accumulate a large number of energetic antiprotons in an accelerator ring. These were used in experiment where antiprotons and protons of high energy were brought to collide. In these experiments W and Z particles were discovered in 1983.

5.6.2 Quantum Gravity

Many of the physicists already mentioned in the previous section not only wrote papers on how to combine quantum theory with special relativity to describe quantum electrodynamics and other aspects of quantum field theory, but they also wrote papers with early ideas for how to combine quantum theory with general relativity in order to describe gravitational effects [Blum and Rickles 2018].

Relativistic quantum theory applied to the gravitational force is called quantum gravity, as illustrated in Fig. 5.57. Since it must incorporate general relativity as well as special relativity, it is far more complex than theories describing the other forces. One way to view the complexity of quantum gravity is to realize that gravitons (particles of the gravitational field) can be produced by anything with mass or energy, but gravitons themselves have energy and can therefore create unlimited numbers of additional gravitons. Another way to view the complexity of quantum gravity is to consider that calculations of particle interactions are made with reference to locations in space and time, yet gravitational interactions warp space and time themselves. For these reasons, even today physicists remain far from a satisfactory theory of quantum gravity (or at least experimental evidence that one of the many proposed approaches to quantum gravity is correct).

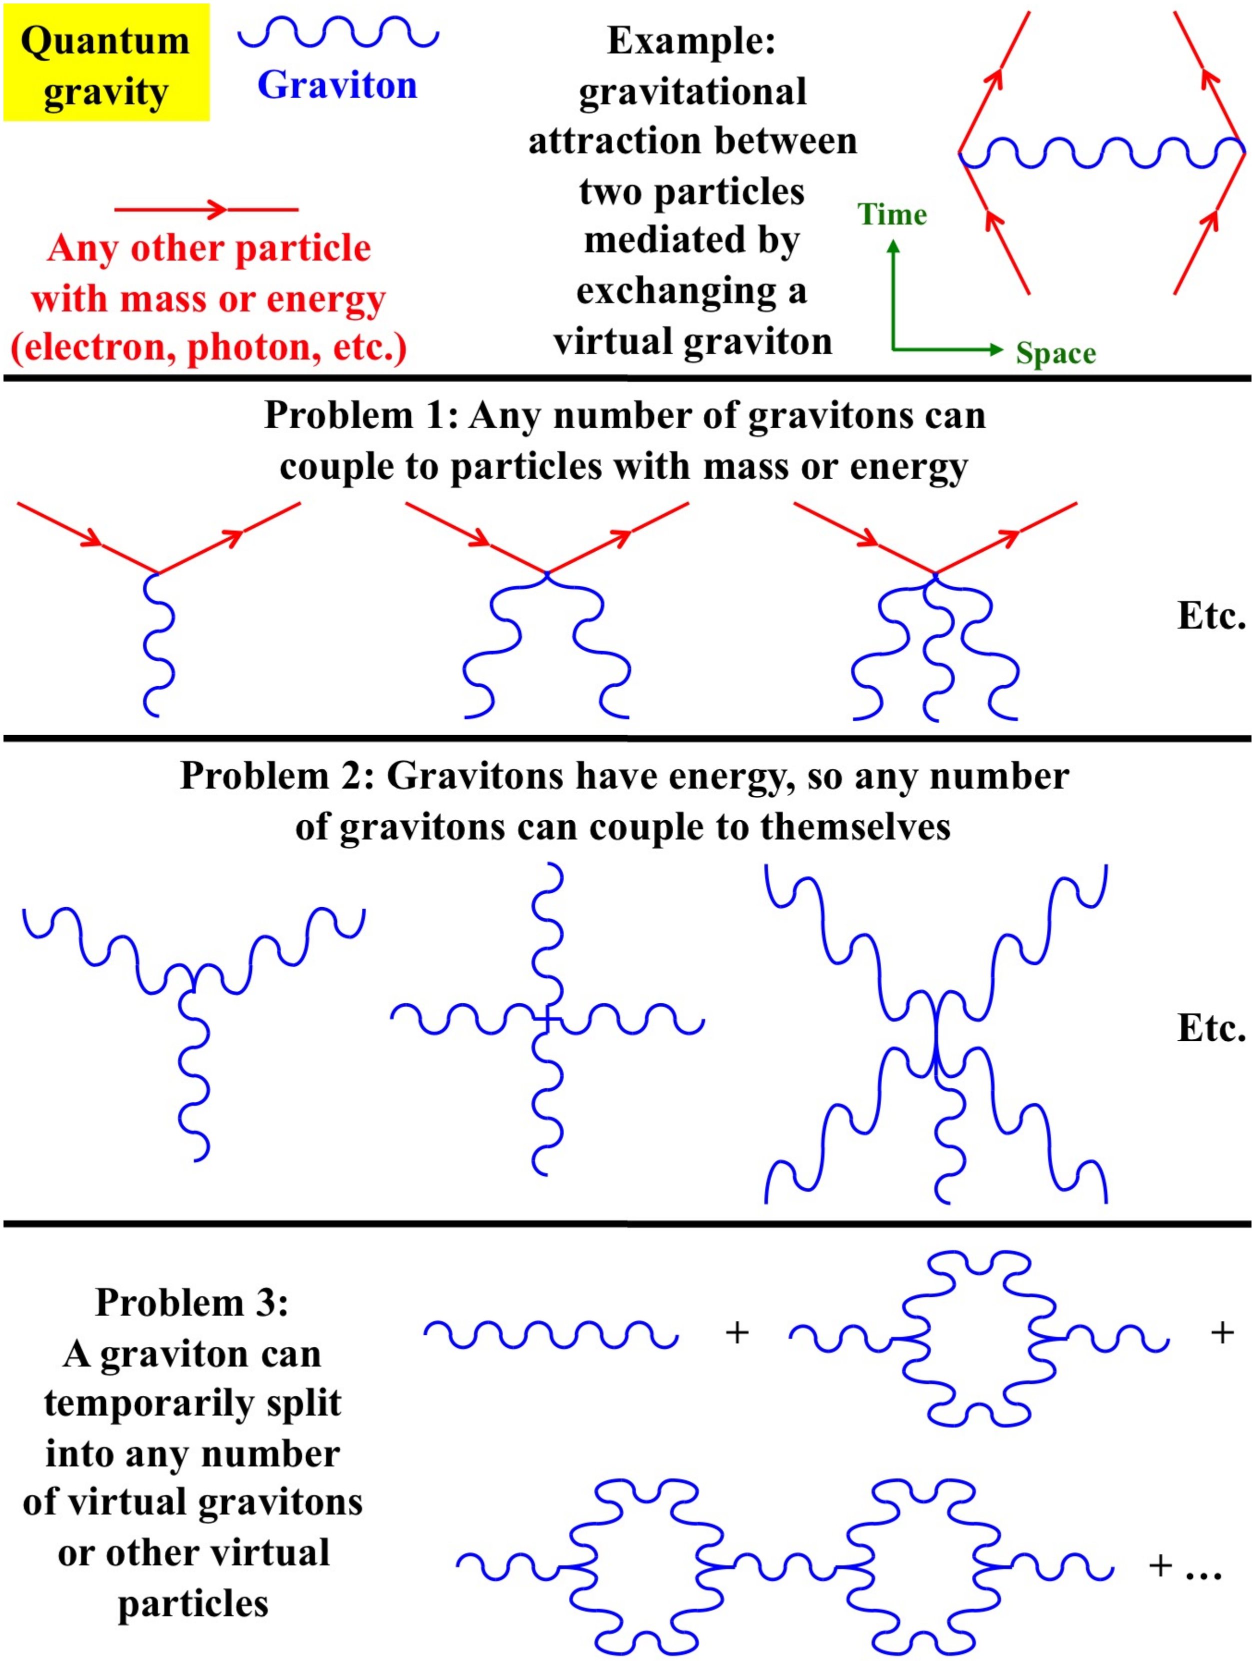
Other physicists bypassed mainstream quantum field theory and focused directly on quantum gravity or other approaches for combining gravity with other fundamental forces and theories [Blum and Rickles 2018; Pais 1982, pp. 325–354].

One of the earliest and most important physicists in this latter category was Theodor Kaluza (German, 1885–1954). In 1919, Kaluza combined Albert Einstein's equations of general relativity with the equations of electromagnetism by using an extra fifth dimension in addition to the usual three spatial dimensions and fourth time dimension. In 1926, Oskar Klein suggested ways to incorporate some aspects of quantum theory as well, so the resulting approach remains known as Kaluza-Klein theory.

Einstein himself was very impressed by Kaluza-Klein theory and spent the rest of his career (until his death in 1955) working on various versions and extensions of it. In that pursuit, Einstein was assisted at different points by Valentine Bargmann (German, 1908–1989) and Peter Bergmann (German, 1915–2002), who in turn each also contributed some of their own original ideas to the field.

Hermann Weyl (German, 1885–1955) and Leopold Infeld (Austrian, 1898–1968) also had some important early ideas about how to combine general relativity with other aspects of physics.

Burkhard Heim (German, 1925–2001) is an interesting case that deserves closer scrutiny. He was badly injured while doing research on novel explosives during the war, then spent the rest of his career pursuing his own ideas for how to combine quantum theory and general relativity [https://www.engon.de/protosimplex/index.htm]. Because his papers were published outside mainstream physics journals and employed Heim's own mathematical notation for his new approaches, his work has never been fully and properly evaluated. Some current or future German-speaking physicists with a detailed knowledge of quantum field theory and quantum gravity research should examine Heim's major papers to determine how sound his reasoning was and whether he had any physics insights that should be more widely known and utilized.



Quantum gravity
Graviton
Any other particle with mass or energy (electron, photon, etc.)
Example: gravitational attraction between two particles mediated by exchanging a virtual graviton
Time
Space
Problem 1: Any number of gravitons can couple to particles with mass or energy
Etc.
Problem 2: Gravitons have energy, so any number of gravitons can couple to themselves
Etc.
Problem 3: A graviton can temporarily split into any number of virtual gravitons or other virtual particles
+
+
+ …

Figure 5.57: Combining special and general relativity with quantum physics yields a theory of quantum gravity, which still suffers from several unresolved mathematical problems.

Chapter 6

Creators and Creations in Electrical and Electromagnetic Engineering

Nehmen Sie zum Beispiel dieses komische Rohr, das sie in Amsterdam verkaufen. Ich habe es genau untersucht. Eine Hülse aus grünem Leder und zwei Linsen, eine so—*er deutet eine konkave Linse an*—, eine so—*er deutet eine konvexe Linse an.* Ich höre, eine vergrößert und eine verkleinert. Jeder vernünftige Mensch würde denken, sie gleichen einander aus. Falsch. Man sieht alles fünfmal so groß durch das Ding. Das ist Ihre Wissenschaft.	You take for example that funny tube that they are selling in Amsterdam. I examined it closely. A casing of green leather and two lenses, one like that—*he indicates by gesture a concave lens*—, one like that—*he indicates a convex lens.* I hear that one enlarges and one reduces. Any sensible person would think that they would cancel each other out. Wrong. One sees everything five times as large through the thing. That is your science.

Bertolt Brecht. 1939. *Leben des Galilei* [*Life of Galileo*]. Scene 1. Ludovico.

This chapter gives an overview of some innovations in electrical and electromagnetic engineering that have played major roles in the modern world and that were invented or discovered by scientists and engineers who were trained in the predominantly German-speaking central European research world in the nineteenth and early twentieth centuries.

Creators from the German-speaking world made major contributions to:[1]

6.1. Electrical equipment and circuits

6.2. Lighting technology

6.3. Communications and recording technologies

6.4. Lasers and holography

6.5. Solid state physics and microelectronics

6.6. Infrared vision and targeting

6.7. Computers and robotics

6.8. Radar and sonar technologies and countermeasures

6.9. Optical microscopes, telescopes, and other optical instruments

6.10. Electron microscopes

---

[1] In addition to specific references that are cited in different areas throughout this chapter, this chapter makes use of general biographical and project information from: ACLS 2000; Albrecht et al. 1992; Ash and Söllner 1996; Bar-Zohar 1967; Bower 1987; Bunch and Hellemans 2004; Challoner 2009; Cornwell 2003; Crim 2018; EB 1911, 2010; Gillispie 1970–1990; Gimbel 1990a; Glatt 1994; Hall 2019a; István Hargittai 2006, 2011; Linda Hunt 1991; Impey et al. 2008; Jacobsen 2014; Koertge 2007; Kragh 2002; Kurowski 1982; Lasby 1971; Lusar 1956, 1971; Medawar and Pyke 2000; Mick 2000; Murray 2003; Nachmansohn 1979; NDB 1953–2020; Neufeld 2012; Nouzille and Huwart 1999; O'Reagan 2014, 2019; Porter 1994; Charles Walker 1946; Peter Watson 2010; Weitensfelder 2009.

For general overviews of large portions of the history of electrical and electromagnetic engineering in the German-speaking world, see: Buchheim and Sonnemann 1990; Bunch and Hellemans 2004 Cardwell 1995; Challoner 2009; Gerhart Göbel 1953; Gööck 2000; Heckl 2010, 2011; Heßler 2012; Hickethier 1998; Jankowsky 2000; König 2000, 2009; König and Schneider 2007; Ludwig 1974; Lundgreen and Grelon 1994; Radkau 1989, 2016; Technisches Museum Wien 2011; von Weiher 1983; Weitensfelder 2009, 2013; https://www.cdvandt.org; https://www.gfgf.org; https://www.radiomuseum.org.

I have deliberately left a blank space where images of some creators or creations should go. Those are people or projects that I felt were important enough that they should definitely be shown in this book, yet I have not yet been able to locate a suitable image that I have permission to use, despite my searches in Europe and in the United States. If readers have any relevant images and could send them to me, I would be very grateful and will include them in future editions of this book. Even where a suitable photo cannot be located, I believe that leaving a blank space pays tribute both to the scientific importance of that creator or creation and to how that historical fact has been very nearly forgotten.

To supplement this chapter, Appendix B provides examples of key documents on transistors, printed circuits and multi-pin connectors, integrated circuits, light emitting diodes (LEDs), etc. These documents demonstrate that German-speaking research groups invented, developed, and demonstrated those revolutionary microelectronics technologies many years before Bell Laboratories and other non-German firms claimed to have officially "invented" them. Moreover, the documents show numerous examples of how the relevant technical information was transferred from the German-speaking world to those firms.

Similarly, Appendix C provides considerable evidence for how directed energy technologies were developed within the German-speaking world and then transferred to other countries. Those directed energy technologies include not only lasers, but also particle beams and X-rays, electromagnetic pulse weapons, focused sound waves, and electromagnetic railguns.

Scientists from the German-speaking world also made numerous contributions to overlapping and related areas listed in other chapters, especially Chapter 5 (physics).

In September 1945, R. P. Linstead and T. J. Betts, the British and American chairs of the Combined Intelligence Objectives Subcommittee (CIOS), listed examples of several German innovations in electronics that would be copied by other countries [AFHRA A5186 electronic version pp. 904–1026, Ch. 4, pp. 38–40]:

> 1. The "Schornsteinfeger" project of radar camouflage is of definite interest. German scientists were discovered to have developed various types of anti-radar coverings which would prevent radar detection. These coverings were applied and used operationally in coating submarine "Schnorkels." Still further applications were contemplated by German experts engaged on this project.
>
> 2. Enemy development of Continuous Wave Transmission Navigational Aids was found to be well advanced. German equipment was capable of greater accuracy and greater range than any hitherto known. Fundamental research data was obtained concerning propagation conditions for use in CW Transmissions.
>
> 3. Infra-red development had received much attention by German experts, and their technique was in advance of that of the Allies. Infra-red was used for night vision to permit night driving of military vehicles, and night sighting and aiming of weapons under conditions of total black-out. Another application was in infra-red searchlights used for the protection of harbor entrances. An entire German combat element had been equipped with infra-red and trained in its use for employment on the Eastern front.
>
> 4. The design of polyrod aerials had been rejected as a development project by British and US authorities. It was discovered that the Germans had achieved successful use of this equipment in many applications. The polyrod aerial possesses important space saving advantages in centimetric radar work.
>
> 5. German scientists had conducted extensive ionospheric investigations. The bulk of their research data has been obtained by Allied scientists.
>
> 6. The enemy had achieved much in the development of materials with a wide range of

> electrical and magnetic properties, and of materials which become superconducting at relatively high temperatures.
>
> 7. Investigation revealed that German radio valve design was generally less advanced than our own. However, particular types of special valve designs have proven of interest.
>
> 8. German electron microscopes, capable of a magnification of 200,000 times, while not more advanced than our own, yield new information of interest.
>
> 9. Examination of anti-jamming circuits used by the Germans has provided new information.
>
> 10. Much valuable information on the use of electronic control and telemetering equipment in guided missiles of all kinds has been obtained.
>
> American experts discovered the Bosch machine and control equipment used for the manufacture of a new type of paper capacitors (condensers). Condensers produced by this process have important advantages over the types generally used in the US and United Kingdom. They are designed with a self-healing feature which will overcome repeated breakdowns resulting from over-voltage surges. One complete unit of this manufacturing equipment has been obtained for evacuation to the US.

In addition to large numbers of government reports, journalists also documented that many revolutionary electronic technologies were transferred out of the German-speaking world after World War II. For example, in October 1946, *Harper's Magazine* reported [Charles Walker 1946]:

> The head of the communications unit of Technical Industrial Intelligence Branch opened his desk drawer and took out the tiniest vacuum tube I had ever seen. It was about half thumb-size.
>
> *Notice it is heavy porcelain—not glass—and thus virtually indestructible. It is a thousand watt—one-tenth the size of similar American tubes. Today our manufacturers know the secret of making it. . . . And here's something. . . .*
>
> He pulled some brown, papery-looking ribbon off a spool. It was a quarter-inch wide, with a dull and a shiny side.
>
> "That's Magnetophone tape," he said. "It's plastic, metallized on one side with iron oxide. In Germany that supplanted phonograph recordings. A day's radio program can be magnetized on one reel. You can demagnetize it, wipe it off and put a new program on at any time. No needle; so absolutely no noise or record wear. An hour-long reel costs fifty cents." He showed me then what had been two of the most closely-guarded, technical secrets of the war: the infra-red device which the Germans invented for seeing at night, and the remarkable diminutive generator which operated it. German cars could drive at any speed in a total blackout, seeing objects clear as day two hundred meters ahead. Tanks with this device could spot targets two miles away. As a sniper scope it enabled German riflemen to pick off a man in total blackness.

There was a sighting tube, and a selenium screen out front. The screen caught the incoming infra-red light, which drove electrons from the selenium along the tube to another screen which was electrically charged and fluorescent. A visible image appeared on this screen. Its clearness and its accuracy for aiming purposes were phenomenal. Inside the tube, distortion of the stream of electrons by the earth's magnetism was even allowed for!

The diminutive generator—five inches across—stepped up current from an ordinary flashlight battery to 15,000 volts. It had a walnut-sized motor which spun a rotor at 10,000 rpm—so fast that originally it had destroyed all lubricants with the great amount of ozone it produced. The Germans had developed a new grease: chlorinated paraffin oil. The generator then ran 3,000 hours!

A canvas bag on the sniper's back housed the device. His rifle had two triggers. He pressed one for a few seconds to operate the generator and the scope. Then the other, to kill his man in the dark. "That captured secret," my guide declared, "we first used at Okinawa—to the bewilderment of the Japs."

We got, in addition, among these prize secrets, the technique and the machine for making the world's most remarkable electric condenser. Millions of condensers are essential to the radio and radar industry. Our condensers were always made of metal foil. This one is made of paper, coated with 1/250,000 of an inch of vaporized zinc. Forty per cent smaller, twenty per cent cheaper than our condensers, it is also self-healing. That is, if a breakdown occurs (like a fuse blowing out), the zinc film evaporates, the paper immediately insulates, and the condenser is right again. It keeps on working through multiple breakdowns—at fifty per cent higher voltage than our condensers! To most American radio experts this is magic, double-distilled.

6.1 Electrical Equipment and Circuits

German-speaking scientists led the discovery of electrical principles and the application of those principles to create essential types of electrical equipment and circuits.

In 1820, Johann Schweigger (German states, 1779–1857) developed the galvanometer for measuring electric current. See Fig. 6.1.

Using galvanometers and different electrical conductors, Georg Ohm (German states, 1789–1854, Fig. 6.1) studied the electrical properties of simple circuits. He demonstrated that the voltage difference V across an electrical component depends on the current I through the component and the electrical resistance R of the component, in accordance with the equation $V = IR$, which is now known as Ohm's law. Oxford University's *Biographical Dictionary of Scientists* explained how Ohm arrived at his conclusions [Porter 1994, p. 390]:

> Ohm began the work that led him to his law of electricity in 1825. He investigated the amount of electromagnetic force produced in a wire carrying a current[...] Ohm found that a longer wire produced a greater loss in electromagnetic force. [...]
>
> From this, Ohm reached the more general statement that the current is equal to the tension (emf or potential difference) divided by the overall resistance of the circuit, thus expressing the law in the form known as Ohm's law.
>
> Ohm went on to use an electroscope to measure how the tension varied at different points along a conductor to verify his law, and presented his arguments in mathematical form in his great work of 1827. He made a useful analogy with the flow of heat through a conductor, pointing out that an electric current flows through a conductor of varying resistance from one tension or potential to another to produce a potential difference, just as heat flows through a conductor of varying conductivity from one temperature to another to produce a temperature difference. [...]
>
> Ohm's derivation of a basic law of nature from experiment was a classic piece of scientific deduction.

Andreas von Ettingshausen (Austrian, 1796–1878, Fig. 6.1) designed the first machine to use electromagnetic induction to generate power.

Heinrich Lenz (Baltic German, 1804–1865, Fig. 6.1) formulated what is now known as Lenz's law, which describes how a changing magnetic field induces electric currents in nearby conductors that create new magnetic fields opposing the changing field. He also discovered that the power P consumed by an electric circuit depends on the current I flowing through the circuit and the electrical resistance R of the circuit, $P = I^2R$.

Heinrich Rühmkorff (German, 1803–1877) developed improved magnetic induction coils, now called Rühmkorff coils, and used them in a variety of applications such as AC transformers and high-voltage generators. See Fig. 6.2.

Werner von Siemens (German, 1816–1892, Figs. 6.3 and 6.22) began his career by creating more sophisticated telegraphs that could point to individual letters, and went on to invent and build a wide range of additional electrical innovations such as electric generators (dynamos), electric motors, transformers, electric elevators, and electric trains [Bähr 2016; von Siemens 1895]. The American Council of Learned Societies noted [ACLS 2000, p. 810]:

> First successful invention was an improved process for gold- and silverplating. After improving upon the indicator telegraph of Wheatstone, he developed an entire telegraph system; in 1847, together with Halske, he founded the Telegraphenbauanstalt von Siemens & Halske to manufacture and construct telegraph systems, eventually expanding to London, St. Petersburg, and Vienna. Helped design the first special cable-laying ship, the *Faraday*, and organized and constructed the Indo-European telegraph from London to Calcutta (1870). His most outstanding contribution was his discovery of the dynamo principle and its practical applications to streetcars and mine locomotives, in electrolysis, and in central generating stations.

Gustav Kirchhoff (German, 1824–1887) worked in many areas of physics, chemistry, and engineering (see also pp. 427, 599, 858, 915, and 957). He discovered a number of physical laws that now have his name attached to them, including laws illustrated in Fig. 6.4 that describe the current and voltage in electric circuits. Oxford University's *Biographical Dictionary of Scientists* summarized his contributions to electrical engineering and electromagnetism [Porter 1994, p. 390]:

> Kirchhoff made his first important contribution to physics while still a student. In 1845 and 1846 he extended Ohm's law to networks of conductors and derived the laws known as Kirchhoff's laws that determine the value of the current and potential at any point in a network. He went on to consider electrostatic charge and in 1849 showed that electrostatic potential is identical to tension, thus unifying static and current electricity. Kirchhoff made another fundamental discovery in electricity in 1857 by showing theoretically that an oscillating current is propagated in a conductor of zero resistance at the velocity of light. This was important in the development in the 1860s of the electromagnetic theory of light[...]

As shown in Fig. 6.5, Johann Sigmund Schuckert (German, 1846–1895) improved electric generators and motors, and also created some of the first lighting systems for streets and buildings in the 1870s. His company, Schuckert & Co., competed with the Siemens company to develop and sell new electrical products. After the deaths of their respective founders, the two companies merged.

František Křižík (Austrian/Czech, 1847–1941) created electric generators, electric motors, electric trains, electric cars, improved arc lamps, etc. (Fig. 6.6).[2] The company he founded, Krizik Works, continued to be an important high-tech industrial center during World War II and the postwar Soviet occupation of Czechoslovakia (e.g., pp. 3987–3998).

Nikola Tesla (Serbo-Croatian, educated in Austria, 1856–1943) invented a complete AC (alternating current) electric power generation, distribution, and usage system for the Westinghouse company in the United States. He also created a wide range of other revolutionary electrical innovations [Cheney 1981; Cheney and Uth 1999; Tesla 1893, 1904, 1919, 1940]. See Fig. 6.7. Tesla biographer Margaret Cheney summed up his impact [Cheney and Uth 1999, pp. vi–vii]:

> Tesla is indisputably the father of alternating current power generation and transmission. His AC technology, first introduced on a large scale at Niagara Falls in 1896, remains unchanged and unchallenged to this day. The same holds true for Tesla's "Apparatus for Transmission of Electrical Energy," patented in 1900, which is still the basis for transmitting and receiving all radio and television signals. These two technologies alone merit the recognition and gratitude of every inhabitant on this planet.
>
> Like other great inventors, Tesla was a true Renaissance man. He turned fresh loam across half-a-dozen fields of science. He patented hundreds of inventions, crafted his own tools, built his own machines, practiced and consulted as an electrical engineer, handled his own press relations with dexterity and *élan*, and was even known to write poetry. Not only did this 19th-century polymath perform such heavy roles under one hat, he was also an environmentalist, a health and nutrition advocate, a philosopher, and many would say a visionary genius.
>
> Tesla was a "heroic" inventor—something we need more of today. He looked at invention as a way to improve the lot of mankind, not just a means of enhancing wealth, or meeting the demands of the marketplace. [...]
>
> Though few inventors have contributed more to the development of the United States as a world power, the prestigious Smithsonian Institution has never substantially acknowledged Tesla's contribution. His alternating current generator, for example, is included in the museum's exhibit on Thomas Edison. The Institution has also been reluctant to credit Tesla's critical role in the invention of radio even though the U.S. Supreme Court affirmed his patent priority over Marconi in 1943. [...]
>
> As a result of this historical bias, Tesla's major inventions are usually attributed to others. [...]
>
> Every time we turn on a light, or a radio, or operate a remote control we continue his legacy. His name should be respected everywhere electricity flows.

As illustrated in Fig. 6.8, Charles (Karl) Steinmetz (German, 1865–1923) invented a complete AC electric power generation, distribution, and usage system for the rival General Electric company in the United States. The *Encyclopedia Britannica* listed some of his key insights [EB 2010]:

> Steinmetz' experiments on power losses in the magnetic materials used in electrical machinery led to his first important work, the law of hysteresis. This law deals with the power loss that occurs in all electrical devices when magnetic action is converted to unusable heat. Until that time the power losses in motors, generators, transformers, and other electrically powered machines could be known only after they were built. Once

> Steinmetz had found the law governing hysteresis loss, engineers could calculate and minimize losses of electric power due to magnetism in their designs.
>
> His second contribution was a practical method for making calculations concerning alternating current circuits. This method was another example of using mathematical aids for engineering the design of machinery and power lines, so that the performance of the electrical system could be predicted in advance. This accomplishment was largely responsible for the rapid progress made in the commercial introduction of alternating-current apparatus. [...]
>
> Steinmetz' third major achievement was in the theory of electrical transients—that is, changes in electrical circuits of very short duration. A prime example of this phenomenon is lightning, and Steinmetz' investigation of lightning phenomena resulted in his theory of traveling waves and opened the way for his development of devices to protect high-power transmission lines from lightning bolts.

Brothers Wilhelm Emil Fein (German, 1842–1898) and Carl Fein (German, 18??–19??) invented the electric hand drill in 1895. See Fig. 6.9.

6.2 Lighting Technology

Creators from the German-speaking world pioneered all major categories of lighting science and technology. They developed spectroscopy to study visible light, and also discovered infrared and ultraviolet light (Section 6.2.1). They were directly responsible for inventing and developing all major types of artificial lighting—incandescent light bulbs (Section 6.2.2), fluorescent light tubes and their variations (Section 6.2.3), and light emitting diodes or LEDs (Section 6.2.4).

6.2.1 Tools for Analyzing the Visible Spectrum, Infrared, and Ultraviolet Light

Spectroscopy, the quantitative separation and measurement of different colors or wavelengths in light, was developed and demonstrated by Joseph von Fraunhofer (Bavarian, 1787–1826), Robert Bunsen (German, 1811–1899), and Gustav Kirchhoff (German, 1824–1887). See Figs. 3.4 and 6.10.

Using spectroscopy to search for energy beyond the colors of visible light, Friedrich Wilhelm (William) Herschel (Hanover, 1738–1822) discovered infrared light in 1800 [Herschel 1800]. See p. 1134. He also discovered the planet Uranus and made several other important astronomical discoveries (p. 802). For more information on infrared technologies, see Section 6.6.

Using spectroscopy in a very similar fashion to search beyond visible light, Johann Ritter (Prussian/Bavarian, 1776–1810) discovered ultraviolet light in 1801 (Fig. 6.10).

6.2.2 Incandescent Light Bulbs

There is significant evidence that Heinrich Göbel (German, 1818–1893) invented the first fully functional incandescent light bulb in 1854, 25 years before the much more famous light bulbs from Thomas Edison's laboratory.[3] See Fig. 6.11. Modern historians and archivists should examine Göbel's work more closely to clarify exactly what he did.

Even the light bulbs that Thomas Edison's laboratory produced in 1879 were heavily dependent upon German-speaking creators whom Edison employed. Those creators included:[4]

- Leonhard Sigmund Bergmann (German, 1851–1927, shown in Fig. 6.12) studied engineering in Thuringia. He was recruited by Edison in 1875, and he played an important role in the development of Edison's versions of the phonograph, telephone, and incandescent light bulb. After that, he worked relatively independently of Edison to produce a variety of electrical and mechanical devices in the United States. Around 1890, Bergmann returned to Germany, where he built up an industrial empire producing everything from electrical systems to steam turbines to automobiles.

---

[3] https://data.tmw.at/object/281276; https://www.zobodat.at/pdf/VeroeffFerd_83_0165-0184.pdf; Paturi 1998, pp. 338–339. For a contrary opinion see Rohde 2007.

[4] Conot 1979; Josephson 1959; http://www.lamptech.co.uk; https://ethw.org/John_Kruesi

- Ludwig Karl Böhm (German, 1859–after 1907, Fig. 6.13) was a student and assistant of Heinrich Geissler, a German inventor of electric lighting (p. 958), during the period 1871–1878. During the crucial period 1879–1880, he worked in Edison's laboratory, where he drew upon his previous experience to create the vacuum pumps, glass envelopes, electrical assemblies, and other key details for the first incandescent lamps that were produced and patented there. He appears to have become quickly disillusioned with Edison and spent the rest of his life working for other companies or for himself. During his life, Böhm produced an astonishing variety of inventions, including multiple types of electric lights, improved vacuum pumps, refrigerated railroad cars, paper-making machines, acetylene gas generators, carbide furnaces, automated money-handling machines, etc.

- Johann Heinrich "John" Krüsi (Swiss, 1843–1899, Fig. 6.14) was a skilled machinist and machine maker who was educated and worked in Europe, then was recruited by Edison in 1872. He became the head machinist in Edison's lab, where he either invented or directly helped to invent the Edison phonograph. After that, he worked on the development of incandescent light bulbs, as well as other associated electrical and mechanical components and inventions.

Thomas Edison and his companies also made use of the innovations of a number of other creators from the German-speaking world, including Robert Bosch (p. 1349), Johann Sigmund Schuckert (p. 952), Charles Steinmetz (p. 955), and Nikola Tesla (p. 954). The accumulated mythology surrounding Edison should be carefully reexamined by modern historians to assign proper credit for the innovations to the appropriate people.[5]

Whereas the first incandescent light bulbs used short-lived, soot-forming carbon filaments, German-speaking creators developed greatly improved incandescent bulbs that used longer-lived, cleaner, and more efficient metal filaments:

- Walther Nernst (German, 1864–1941, Fig. 6.15) invented zirconium filaments in 1897.

- Carl Auer von Welsbach (Austrian, 1858–1929, Fig. 6.15) invented osmium filaments in 1898. (He also invented the gaslight mantle in 1885 and the flint metal lighter in 1903, and he founded Auergesellschaft, Treibacher Industrie, and Osram.)

- Werner von Bolton (German, 1868–1912) and Otto Feuerlein (Swiss, 1863–1930) invented tantalum filaments in 1902. See Fig. 6.16.

- Alexander Just (German, 1874–1937) and Franjo Hanaman (Austro-Hungarian/Croatian, 1878–1941) invented tungsten filaments in 1904, and they have been widely used ever since (Fig. 6.16).

6.2.3 Gas Discharge and Fluorescent Light Tubes

Heinrich Geissler (German, 1814–1879), Julius Plücker (German states, 1801–1868), and Johann Hittorf (German, 1824–1914) developed and tested early high-voltage gas discharge tubes that were ultimately diversified into vacuum tubes, X-ray tubes, cathode ray tubes, neon lighting tubes, and fluorescent lighting tubes. See Fig. 6.17.

---

[5] There also appear to have been other inventors in the English-speaking world, such as William Sawyer (U.S., 1850–1883) and Joseph Swan (English, 1828–1914), whose accomplishments have been unfairly slighted by all of the hagiography focused on Edison.

As shown in Fig. 6.18, Leo Arons (German, 1860–1919) modified high-voltage gas discharge tubes to create the mercury vapor lamp in 1892.

Edmund Germer (German, 1901–1987), Friedrich Meyer (German?, 18??–19??), and Hans Spanner (German?, 18??–19??) further modified high-voltage gas discharge tubes to invent modern fluorescent lighting tubes in 1926. Specifically, they coated mercury vapor lamp tubes with fluorescent chemical pigments to absorb the ultraviolet light emitted by the mercury and reemit that energy as a range of visible light. See Fig. 6.19.

Nikolaus Riehl (German, 1901–1990, p. 1625), one of the leading scientists of Auergesellschaft, also made important contributions to chemical pigments for fluorescent lighting and to the optical spectroscopy of solid materials.

Both before and after World War II, these lighting technologies were transferred from the German-speaking world to other countries. BIOS 395, *German Fluorescent Lamp Industry and Phosphor Chemical Manufacture*, pp. 3 and 5, provides an example of the transfer of information on improved fluorescent light tubes to the United Kingdom and United States:

> REPORT 2—DISCUSSION WITH DR. ABRAHAMOZIK, FORMERLY RESEARCH CHEMIST OF THE WELT-POST INSTITUTE, HEIDELBERG. 14.11.1945.
>
> [...] With Dr. Lappe, a physicist, he had been engaged on the preparation of metallic sulphides, selenides and tellurides by new methods employing furnacing at ultrahigh-pressures circa 1,000 atmospheres. The object was to obtain improved efficiency of transformation of long wave U.V. into visible radiation and secondly to produce fluorescent powders responsive to infra-red radiation of long wavelength corresponding with 400^oC radiators.
>
> Ultra-Violet Phosphors:
>
> A large range of possible substances had been investigated of which the most effective was found to be zinc sulphide containing 5% zinc selenide activated with 0.0001% Cu, up to 1% Cu. This material was stated to be some 30% to 50% more efficient than a simple zinc sulphide produced by the same method.
>
> I.R. Phosphors:
>
> To produce powders responsive to long wavelength I.R. radiation—zinc, lead, mercury, cadmium sulphides, selenides and tellurides had been investigated. The zinc sulphide + 5% selenide was good and the telluride compound was probably better but less was known about the properties.
>
> These latter compounds were used in receiving circuits for detecting I.R. by employing the phosphor as the dielectric of a condenser fitted in a sensitive valve receiver. Reception

> of I.R. radiation was indicated by circuit changes resulting from changes in the dielectric constant of the phosphor.

Gilles Holst (Dutch, 1886–1968) and Willem Uyterhoeven (Dutch, 18??–19??) invented sodium vapor lamps in 1932, as shown in Fig. 6.20. Holst was the research director at the Philips Eindhoven laboratory [VanDelft 2014], which was closely tied to the rest of the predominantly German-speaking research world from the late nineteenth century through World War II, including work on electronics, communications, and directed energy beams.[6] Holst was also involved in research toward the development of transistors (pp. 1056–1057 and 2686–2689).

6.2.4 Light Emitting Diodes (LEDs)

Bernhard Gudden (German, 1892–1945), Robert Pohl (German, 1884–1976), Zoltan Bay (Hungarian, 1900–1992), György Szigeti (Hungarian, 1905–1978), and Kurt Lehovec (Bohemian/Austrian/Czech, 1918–2012) developed light emitting diodes (LEDs). See pp. 1106–1108 and Section B.4.

DEUTSCHES REICH

AUSGEGEBEN AM
6. DEZEMBER 1937

REICHSPATENTAMT

PATENTSCHRIFT

№ 653 902

KLASSE 21f GRUPPE 82 01

N 37344 VIII c/21 f

Tag der Bekanntmachung über die Erteilung des Patents: 18. November 1937

Philips Patentverwaltung G. m. b. H. in Berlin*)

Mit einem entlüfteten Raum umgebene, insbesondere zur Lichtausstrahlung dienende gasgefüllte elektrische Entladungsröhre

Zusatz zum Patent 652 752

Patentiert im Deutschen Reiche vom 30. Oktober 1934 ab
